CUK-H06724-156-RR286

NATURE

A WEEKLY JOURNAL OF SCIENCE

"To the solid ground
Of nature trusts the Mind that builds for aye" —WORDSWORTH

156

Volume 156

JULY 7, 1945, to DECEMBER 29, 1945

LONDON
MACMILLAN AND CO., LTD.
NEW YORK: THE MACMILLAN COMPANY

DATES and PAGINATION of WEEKLY ISSUES

Serial No.	*Date of Issue*	*Pagination*
3949	July 7	1–28
3950	,, 14	29–62
3951	,, 21	63–90
3952	,, 28	91–124
3953	August 4	125–152
3954	,, 11	153–186
3955	,, 18	187–214
3956	,, 25	215–248
3957	September 1	249–276
3958	,, 8	277–310
3959	,, 15	311–344
3960	,, 22	345–372
3961	,, 29	373–400
3962	October 6	401–428
3963	,, 13	429–456
3964	,, 20	457–484
3965	,, 27	485–512
3966	November 3	513–546
3967	,, 10	547–580
3968	,, 17	581–608
3969	,, 24	609–642
3970	December 1	643–670
3971	,, 8	671–698
3972	,, 15	699–726
3973	,, 22	727–760
3974	,, 29	761–788

NAME INDEX

of Sciences of the U S.S.R. : Conference on Viscosity of
uids and Colloidal Solutions, 147
. Anniversary Celebrations, 221
ction of Academician Sergei Vavilov as president, 230
stronomical Institute of the) . Ephemerides for the Determination of Time Corrections by Equal Altitudes (Zinger's Method) for
1944, 16
uaire astronomique de l'URSS pour l'an 1944, 17
ry Food Factors Committee (Vitamin A Sub-Committee of the) ·
periment on the Human Requirement of Vitamin A and of
ane, 11
J. K. : Surface Chemistry in the U.S.S R., 284
Obituary by Dr. A T. Hopwood, 470
Roger : Awarded the Davy Medal of the Royal Society, 596,
C. : Time Factor in Surface Tension Measurement, 600
Retirement of Dr. C. F. Goodeve from the post of deputy
ller for research and development, 472
ent of A P. Rowe as deputy controller for research and
pment, 472
E. D. Physiology in the U S S R., 222
Magendie (1783–1855), *review*, 316
College of · Appointment of the Board of Governors, 200
ment of E. F Relf as principal, 623
N. · Elected to an Imperial Chemical Industries Fellowship at
ridge, 17
Bureaux, Imperial . Joint Publication No. 7 on *Imperata*
ylindrica, 342
ultural Economics Research Institute, Oxford : Retirement of Dr. C S. Orwin, 500
Appointment of Prof. A. W Ashby as director, 624
icultural Research Council . Appointment of Prof R. G. White and Dr. C H Waddington to its scientific staff, 231
culture and Fisheries, Ministry of : Advisory Leaflet No. 315 on Weed Control in Cereals, 330
nt of Dr. E. S. Russell from the post of director of fishery
ations, 687
ent of R R. Enfield as chief economic adviser, 687
nent of D. A. E. Harkness as principal assistant secretary in
of the Economics and Statistics Division, 687
Appointment of Dr. H R. Hulme as scientific adviser, 745
blishment, Royal Pamphlet on Aeronautical Training, 78
kle, Dr J., and) : Flow of Water through Very Narrow
als and Attempts to Measure Thermomechanical Effects in
, 367
and others (edited by) · Essays in Anthropology Presented
hadur Sarat Chandra Roy, *review* by Prof. J. H. Hutton, 66
of F. . *Death* of, 596
ield-Marshal the Hon. Sir Harold . Elected an honorary
of the Institution of Civil Engineers, 598
of. W H. · Presidential Address to Section II of the Royal
of Canada, 271
lannes . A New Theory of the Origin of the Planets, 378
A. H : A Simple Trap for Catching Fleas, 501
entific Research Institute of Plant Industry of the U.S.S.R. ·
n to Leningrad, 745
Frank . Production of Difference Tones, 84
and others . Use of Carbon Dioxide in Fruit Storage and
rt, 178
cival · Lognormal Distributions, 746
· Colorimetric Analysis, *review* by A L. Bacharach, 434
lemy of Tropical Medicine · Theobald Smith Gold Medal
to Dr. C M. Wenyon, 473
nical Society : Appointment of Dr. Cornelia T. Snell as
an of the New York Section, 230
armaceutical Manufacturers' Association Award of Distinction
nted to the National Research Council of the United States
nal Academy of Sciences, 575
ilosophical Society and the U S. National Academy of Sciences
meeting on Atomic Energy and its Implications, 687
J. (Kent-Jones, Dr D. W., and) : Bread in Jersey during
an Occupation, 336
r John : Research in relation to Reconstruction, 660
and Reconstruction, 711, 733
Dr. H. B . Mammary Tumours in Mice, 787
f. E. N. da C. : Effect of Alpha-Ray Bombardment on Glide
al *Single Crystals*, 113
orary Physics in the U.S S R., 223
F. : Scientific Film Needs in Technical Training, 426
and the Burmah Oil Companies · Offer of £750 a year to
eological Society of London to defray the costs of an instruc-
al tour for students, 533
ehaviour, Institute for the Study of · Election of officers, 566
Production, British Society of : Discussion on Pig Production, 454
, Prof. H. E. : *Obituary* by Dr. Sarah Barnes, 328
opological Institute, Royal, and the Social Psychology Section of the British Psychological Society · Discussion on the Scapegoat in Modern Europe, 380
roff, Prof George : Time *Dependence of Interfacial* Tension and
Density In Solutions, 301

Appleton, Sir Edward . Departure of Long-Wave Solar Radiation from Black-Body Intensity, 534
  Elected an honorary member of the Institution of Civil Engineers, 598
Archbold, H. K Some Factors concerned in the Process of Starch Storage in the Barley Grain, 70
Architects (Naval), Institution of Appointment of Capt Arthur Dyce Duckworth as secretary, 502
Arden, R. W Awarded a fourth prize by the Institute of Welding, 473
Aristotelian Society : Proceedings of the, New Series, Vol. 44, Session 1943–1944, *review* by Prof. A. D. Ritchie, 33
Aristotle's Criticism of Plato and the Academy (Harold Cherniss), Vol. 1, *review* by Prof. A. E. Taylor, 647
Armstrong, Dr. E F. . *Obituary* of Sir David Milne-Watson, 499
  The Royal College of Chemistry, 524
  A United Nations Educational and Cultural Organisation—Introduction, 553
  The Allied Plan for Education, 708
  Death of, 742
Arthur, D. R : Hatching of the Egg of *Ixodes ricinus* L., 538
Arts, Royal Society of : Prize and Award under the Thomas Gray Memorial Trust, 17
Aschner, Dr. M , and others : Production of Extracellular Starch in Cultures of Capsulated Yeasts, 295
Ashby, Prof. A. W. · Appointed director of the Agricultural Economics Research Institute, Oxford, 624
Ashcroft, Miss Lucy : *Death* of, 415
Ashworth, Dr. J. R · Behaviour of Ultra-Violet and Daylight Rays in the Solar Cycle, 115
Asiatic Society of Bengal, Royal : Conference on Indology and Oriental Culture, 687
ASLIB : Conference on Microfilm and other Means of Documentary Reproduction, 24
  Report of the Proceedings of the Nineteenth Conference, 108
  Twentieth Annual Conference, 232, 605
Association of Applied Biologists · Report on the Recruitment and Training of Plant Pathologists in Great Britain, 724
Association for Planning and Regional Reconstruction : Development of its Information Service, 775
Association of Scientific Workers : Appointment of Roy Innes as general secretary, 331
  Discussion on the Inter-relations between the Natural and Social Sciences, 652
  (Leeds Branch) : Conference on Science and Education, 56
Association of Special Libraries and Information Bureaux · Conference on Microfilm and other Means of Documentary Reproduction, 24
  Report of the Proceedings of the Nineteenth Conference, 108
  Twentieth Annual Conference, 232, 605
Association of University Professors and Lecturers of the Allied Countries in Great Britain : Some Comparisons between Universities (Proceedings of the Second Education conference), 183
Association of University Teachers · Second Report on University Developments, 311
Astbury, Dr. W. T. : Structure of Biological Fibres and the Problem of Muscle, 89
  X-Ray Adventures among the Proteins and other Molecular Giants, 427
  Appointed to the chair of biomolecular structure in the University of Leeds, 501, 531 ; work of, 531
Aston, Dr. F. W. : *Death* of, 657
Asundi, Prof. R. K., and Padhye, M. R. : Near Ultra-Violet Emission Bands of Benzene, 368
Asundi, Prof. R. K , and Venkateswarlu, P. : Emission Bands of the Fluctuation Type in the Spectrum of Iodine, 452
Atkins, Dr. W R. G. · Autotrophic Flagellates as the Major Constituent of the Oceanic Phytoplankton, 446
  Conditions for the Vernal Increase in the Phytoplankton and a Supposed Lag in the Process, 599
Atzenweiler, L. F. . Pre-War Production and Distribution of Narcotic Drugs and their Raw Materials, 361
Augustinsson, Dr K.-B · Choline Esterases, 303
Austin, H. B · The Merino, *review* by Dr. J E. Nichols, 251
Austin, Prof. James M (Haurwitz, Prof Bernhard, and) Climatology, *review* by Prof D. Brunt, 157
Australian Council for Scientific and Industrial Research : Retirement of Gerald Lightfoot from the secretaryship, 444
  Appointment of G A Cook as secretary, 444
Avery, Dr. O. T . Awarded the Copley Medal of the Royal Society, 596, 694
Aykroyd, Dr W. R. : Organisation of Scientific Research in the British Commonwealth, 758
Azerbaijan Academy of Sciences : Foundation of the, 44

BABBITT, Dr J. D. : Hysteresis in the Adsorption of Water Vapour by Wheat, 265
Babcock and Wilcox, Ltd · Grant of £750 to the University of Leeds for equipment in the Coal Gas and Fuel Industries Department, 502
Bacharach, A. L. : Colour for Analysts, *review*, 434
Bacteriologists (Agricultural), Society of : Name changed to the Society for Applied Bacteriology, 481
  Papers at the Summer Conference, 481

Baddiley, Dr. J. : Elected to an Imperial Chemical Industries Fellowship at Cambridge, 17
Bailey, C R. · Degree of D.Sc. of the University of London conferred on, 108
Bailey, J E. C. : Elected president of the Scientific Instrument Manufacturers' Association of Great Britain, 202
Bailey, Dr. K. · Elected to an Imperial Chemical Industries Fellowship at Cambridge, 17
  Proteins, Amino-Acids and Peptides, *review*, 405
Bailly, J., and Decrop, G. : A propos d'un procédé d'exploration simple de l'état fonctionnel du Foie, 395
Bairstow, Prof. L. . Retirement from the Zaharoff chair of aeronautics in the University of London, 165 , work of, 165
Baker, A L. L. : Appointed to the University of London chair of concrete technology at the Imperial College of Science and Technology, 45
Baker, Frank Collins : The Molluscan Family Planorbidæ, *review* by F. Martin Duncan, 765
Baker, Dr. H. G. · Late Flowering of Horse-Chestnut, 721
Baker, John R. : Science and the Planned State, *review*, 614
Baker, Mrs. Kathleen M. : Use of Hydrochloric Acid for Softening Algal Tissues for Microtome Sections, 479
Baker, Prof. W. : Natural Organic Colouring Matters, *review*, 552
Balint, Edna M., and others : An Introduction to Child Guidance, *review* by Dr Alan Maberly, 157
Balliol, The Master of : The Good and the Clever, 744
Banerjee, B. K., and others : X-Ray Study of the Solution of Alkali Halides in Borax and B_2O_3 Glass Systems, 423
Bangham, Dr. D. H. : The Corrosion of Metals, 435
Barac, G., and others : Les états de carence en Belgique pendant l'occupation Allemande 1940–1944, *review* by Major J Marshall, 551
Barber, D. R. : The 'Green Flash' at Sunset with a near 'Horizon', 146
Barclay-Smith, Prof. E. : *Death* of, 42 ; *obituary* by Prof. A. J. E. Cave, 136
Barclay-Smith, Phyllis Garden Birds, *review*, 34
Barducci, Prof. Teodoro Boza, and others : Control of Internal Boll Rot of the Cotton Plant, caused by Insect Punctures (*Dysdercus* sp.), through Selection of Resistant Strains, 235
Barker, Sir Ernest · Some Comparisons between Universities, 183
Barlow, Dr. H E. M. . Title of University of London professor of electrical engineering conferred on, 566
Barnard, G. A. : A New Test for 2 × 2 Tables, 177, 783
  Economy in Sampling, 208
Barnes, R Bowling, and others : Infra-red Spectroscopy, *review* by Dr. H W. Thompson, 65
Barnes, Dr. Sarah *Obituary* of Prof. H. E. Annett, 328
Barnes, T. W. · Accumulation of Sugars in Barley Seedlings on Very Acid Soil, 692
Barnes, W. H. F. : Appointed to the chair of philosophy in the Durham Division of the University of Durham, 202
Barry, Vincent C., and McNally, Dr. P. A. Inhibitory Action of Dialkyl Succinic Acid Derivatives on the Growth *in vitro* of Acid-fast Bacteria, 48
Bartlett, Prof. F. C. : Appointed a member of the Industrial Health Research Board of the Medical Research Council, 566
Basch, Dr Antonin : The Danube Basin and the German Economic Sphere, *review*, 551
Baskett, Prof. R. G. : Pig Production, 454
Bate-Smith, Dr. E. C., and Bendall, J. R. : Heat Coagulation of Muscle Proteins, 632
Bateman, Dr. L. C. : Photochemical Breakdown of Rubber, 9
Bates, Dr. William H. The Bates Method for Good Sight without Glasses, *review*, 281
Bathe, Greville : The Onandaga Salt Works of the New York State, 1646—1846, 759
Bauchwitz, F. K., and Shoenberg, D. : A New Interference Effect, 142
Bayer, Dr. Augustus : Executed by the Germans in 1942, 416
B.B.C. : Programmes entitled 'Science Magazine', 140
Beakbane, Dr. A. Beryl, and Thompson, Dr Eleanor C. Abnormal Lignification in the Wood of some Apple Trees, 145 , *erratum*, 202
Beale, Dr. G H. · Recent Biological Work in Finland, 357
Beattie, A. G. : Appointed director of agriculture, Nigeria, 445
Beck, Stephan . Spontaneous Regression of Histologically Malignant Tumours Induced in Rabbits by 9 : 10-Dimethyl-1 . 2-Benzanthracene, 238
Bedford College : Appointment of D. W. Harding to the University of London chair of psychology, 108
Bell, Geoffrey : The Film in Science, 426
Bell Telephone Laboratories : New Buildings of, 274
Bellamy, C. V. . Science in Adult Education, 57
Bellamy, Colonel R. G. . Resignation from the lectureship in mechanical engineering in the University of Sheffield, 473
Bendall, J. R. (Bate-Smith, Dr. E. C , and) · Heat Coagulation of Muscle Proteins, 632
Benesch, Dr R. : Biochemical Aspects of Mental Disorder, 103
Benfield, H. : The Place of Science in Primary Schools, 56
Benford, G. A., and others · Univalent Electron Transfers in Aromatic Nitration ?, 688
Bengough, Percy . Appointed a member of the National Research Council of Canada, 416
Benham, Dr. F. C. . Appointed to the University of London chair of commerce at the London School of Economics, 108
Benham, W. E. : A New Occurrence of the Electronic Phase Velocity, 204
Bentwich, Prof. Norman : The Educational and Cultural Organisation of the United Nations, 445
Berenblum, Dr. I. : 3 : 4-Benzpyrene from Coal Tar, 601
Berg, Dr. W. F. : New Basic Concepts in Electrocardiography—The Ventricular Gradient, 590
Bergel, Dr. F. : The Vitamin B_2 Complex, 87
Bergstrom, Sune : Autoxidation of Linoleic Acid, 717
Bernacca, J P. : Appointed entomologist, Uganda, 687
Bernal, Prof. J. D. · Microfilm and other Means of Documentary Reproduction, 26
  A United Nations Educational and Cultural Organisation—A Permanent International Scientific Commission, 557
  Awarded the Royal Medal of the Royal Society, 596, 694
  Information Service as an Essential in the Progress of Science, 605
  The Inter-relations between the Natural and Social Sciences, 652
  Lessons of the War for Scientists, 659
Berry, P. A , and Macbeth, Prof. A Killen : A Tetrabromide of β-Ph landrene, 175
Berthelot, R. : Cosmic Rays, 544
Betekhtin, A. G : Manganese Deposits of the U.S S R., 87
Betts, Prof. Edwin Morris (annotated by) : Thomas Jefferson's Gard Book, 1766–1824, with Relevant Extracts from his other Writing *review* by Dr. E. J Salisbury, 128
Bezssonoff, Dr. N., and Leroux, Dr. Helène Vitamin C Peroxidas Activity, 474
Bhagavantam, Prof. S., and Bhimasenachar, J. : Shear Modes in Nor Piezo-Electric Crystal Plates, 23
Bhatia, A. B. (Krishnan, Prof. K. S., and) . Electrical Resistance of Liqu Metals, 503
Bhattacharjee, S K. (Saha, J C , and) · Artificial Production of Ergot the Tropical Plains of Bengal, 363
Bhimasenachar, J (Bhagavantam, Prof S., and) : Shear Modes in Non Piezo-Electric Crystal Plates, 23
Bibby, Cyril · Sex Education—Aims, Possibilities and Plans, 412, 438
Bielschowsky, F , and Green, Prof. H. N. : An Induced Carcinoma in th Fowl, 780
Bielschowsky, Marian, and Green, Prof. H N. · Synthesis of Adenosin Triphosphate by an Enzyme System from Ischæmic Muscle, 117
Bilibin, Y. A : Post-Jurassic Intrusions of the Aldan Region, Easter Siberia, 178
Biochemical Society and the Nutrition Society · Joint meeting on th Vitamin B_2 Complex, 86
Biological Council Formation of a, 713
Biologists (Applied), Association of . Report on the Recruitment an Training of Plant Pathologists in Great Britain, 724
Bishop, F. P. . The Economics of Advertising, *review*, 765
Bishui, B. M. (Sirkar, Dr. S. C , and) : Fluorescence of Dipropyl Ketone at Low Temperatures, 333
Bissett, C. B. . Appointed deputy director of the Geological Survey Uganda, 687
Bittner, Dr. J. J. Mammary Tumours in Mice, 787
Black, Archibald N. : Appointed Donald Pollock reader in engineering science in the University of Oxford, 417
Blackett, Prof P. M. S . Cosmic Rays, 543
  Obituary of Prof. E. J. Williams, 655
Blackfan, Dr. Kenneth D , and Diamond, Dr Louis K : Atlas of the Blood in Children, *review* by Prof. Thos. B Davie, 192
Blackman, G E. · Appointed Sibthorpian professor of rural economy at the University of Oxford, 262 ; work of, 262
Blackwell, Miss E. M. . Late Flowering of Horse-Chestnut, 721
Blair, Dr. G. W. Scott Viscosity of Liquids and Colloidal Solutions, 147
Blake, Dr. Francis G. : Awarded the United States Typhus Commission Medal, 445
Blaschko, Dr. H , and Duthie, Ruth · Action of Mepacrine on Diamine Oxidase, 113
Bloch, Dr A. . Electromechanical Analogies, 151
Block, Dr. Richard J., and Bolling, Diana · The Amino Acid Composition of Proteins and Foods, *review*, 33
Bloom, H. (Heymann, Dr. E., and) . Activation Energy of Ionic Migration in Molten Salts, 479
Bloxham, J L. (Parkinson, Dr. D , and) The Behaviour of Natural Rubber and GR-S under Repeated Stress Cycles, 11
Blyton, Enid : Faiths of Many Lands (E. Royston Pike), *review*, 34
Boardman, Philip . Patrick Geddes, Maker of the Future, *review* by R. Brightman, 612 , *erratum*, 687
Boerker, Richard H. D. . Behold our Green Mansions, *review* by Prof. F. J. Lewis, 584
Bolin, Rolf L. · Marine Cottid Fishes of California, 395
Bolivar y Urrutia, Don Ignacio : *Obituary* by Dr. B. P. Uvarov, 74
Bolland, J L. (Orr, Dr. W. J C., and) · Thermal Breakdown of Rubber, 9
Bolling, Diana (Block, Dr. Richard J., and) . The Amino Acid Composition of Proteins and Foods, *review*, 33
Boorman, K. E., and others : Enhancement of the Action of Immune Hæm-Agglutinins by Human Serum, 663
Booth, A. D. . Accuracy of Atomic Co-ordinates Derived from Fourier Systems, 51
Borg, Prof. John . *Obituary* by W. B. Turrill, 14
Born, Prof. Max Theoretical Physics in the U S S.R , 325
  Dublin Colloquium, 1945, 704
  Quantum Electrodynamics, 705
  Some Problems of the Theory of Crystals, 705
Born, Prof. Max, and Bradburn, Mary The Raman Effect in Rocksalt, 567
Born, Prof Max, and others : A Photo-Electric Fourier Transformer, 756
Borradaile, Dr. L A *Obituary* by Prof. J. Stanley Gardiner, 622
Bose, Prof. S. R. . Anti-bacterial Action of 'Polyporin' against Typhoid, Cholera, Dysentery and *B. coli*, 171
Bose Research Institute, Calcutta : Annual Report for 1943–44, 696 , Annual Report for 1944–45, 697
Botanic Gardens, Royal, Kew Appointment of Dr. Debabrata Chatterji as assistant for India, 444
Bourne, L. B Hexachloro*cyclo*hexane as an *Insecticide*, 85
Bouvier, Prof. Eugène-Louis *Obituary* by Dr. E. Hindle, 42
Bowden, Dr. F. P., and others · Lubrication of Metal Surfaces by Fatty Acids, 97
Boyazoglu, Dr. A. J. . Elected a fellow of the Royal Society of South Africa, 687
Boyd, Dr. A E. W , and others : Control of Dry Rot of Seed Potatoes by Dusting, 394
Boyd, Prof. J. D , and others · Human Embryology, *review* by Dr. D. V. Davies, 315
Boyland, Dr. E. : Mammary Cancer in Mice, 787
Brabazon of Tara, Lord : Freedom for Scientific Research, 746
Bradburn, Mary (Born, Prof Max, and) : The Raman Effect in Rocksalt, 567
Bradford Dyers' Association, Ltd. . Grant of £1,500 a year for two years to the University of Leeds for the Institution of two research fellowships, 502
Bradley, C. B. · Science and Education, 57
Braestrup, F. W. : Progressive Clines, 337
Bragg, Sir Lawrence : Lectures at the Sorbonne in Paris, 45
  To visit Portugal under the auspices of the British Council, 598
Bragg, Sir Lawrence, and Stokes, A. R · X-Ray Analysis with the Aid of the 'Fly's Eye', 332

Brain, E. Dorothy · Growth Inhibition in Pea Seedlings, 397
Braithwaite, Rachel R., and Clayton, Evelyn B. : A British Freshwater Nemertine, 237
Brakier-Zelkowiecz, T., and others : Les états de carence en Belgique pendant l'occupation Allemande 1940–1944, *review* by Major J. Marshall, 551
Bratley, C. O., and others : Use of Carbon Dioxide in Fruit Storage and Transport, 178
Brenchley, Dr. W. E. : *Obituary* of Dr J. Davidson, 359
Brend, Dr. William A. : Foundations of Human Conflicts, *review* by Dr. William Brown, 314
Brenner, S., and others : Porphyrin Fluorescence in the Livers of Pellagrins in relation to Ultra-Violet Light, 689
Brian, Dr. P. W., and McGowan, J. C. : Viridin, a Highly Fungistatic Substance produced by *Trichoderma viride*, 144
Bridge, J. F. : *Obituary* of Sir William H. Ellis, 290
Brightman, R. : Management of a Special Library, *review*, 406
  Problems of the Modern University, *review*, 432
  Patrick Geddes, *review*, 612 ; *erratum*, 687
Brimble, L. J. F. : Return from a tour of India and Burma, 291
Brindle, H. : Origin and Development of Pharmaceutical Chemistry, 138
Brindley, Dr. G. W ,,and Robinson, Keith Structure of Kaolinite, 661
British Association : Re-opening of the Charles Darwin memorial rooms at Down House, 533
British Association of Chemists : Appointment of J. Stewart Cook as organising secretary, 362
  (London Section) · Open meeting on Social Security for Chemists, 331
British Association for Labour Legislation : The New I.L.O., 231
British Bryological Society : First meeting since June 1939, 626 , *erratum*, 777
British Cotton Industry Research Association . Fellowships, 200, 686
British Council . British Medical Exhibition at the Sao Jose Hospital in Lisbon, 45
  Appointment of Dr. A E. Morgan as educational director, 77
  Establishment of an Argentine-British Medical Centre in Buenos Aires, 107
  Annual Report, 122
  Chinese Visitors to Britain as guests of the, 201
British Ecological Society : Memorandum on the Establishment of an Aerial Unit for Scientific Work, 2
British Grassland Society : First meeting of the, 78
British Industries, Federation of : Appointment of B. J. A. Bard as head of the F.B.I. Research Secretariat and secretary of the F B.I. Industrial Research Committee, 77
British Iron and Steel Research Association : Formation of the, 138
  Appointment of Dr. C. F. Goodeve as director, 138, 472
British, Medical Association (Nutritional Committee of the Jamaica Branch) : Report on Nutrition and Agriculture in Jamaica (Dr. W. E. McCulloch and colleagues), 288
British Museum (Natural History) : Appointment of N. B. Kinnear as keeper in the Department of Zoology, 17
  Retirement of M. A. C. Hinton as keeper of the Department of Zoology, 43
British Psychological Society (Social Psychology Section) and the Royal Anthropological Institute : Discussion on the Scapegoat in Modern Europe, 380
British Rheologists' Club : Conference on Strength of Materials, 306
  Fifth Annual General Meeting, 745
  Re-election of Prof. E. N da C. Andrade as president, 745
British Rheologists' Club, and the Manchester Section of the Oil and Colour Chemists' Association · Discussion on the General Rheological Properties of Suspensions, 745
British Schering Research Institute : Appointment of Dr. J. S. H. Davies as director of research, 626
British Social Hygiene Council and the Town and Country Planning Association : Conference on the Needs and Problems of the Family, 777
British Society of Animal Production : Discussion on Pig Production, 454
Brodetsky, Prof. S. : Science and the University, 57
Bronikovsky, N ·(Graham, H. W., and) : The Genus *Ceratium* in the Pacific and North Atlantic Oceans, 181
Brooks, Dr C. E. P. : The 'Green Flash' at Sunset with a Near Horizon, 368
Brosset, Cyrill : Formation of an Addition Compound of Calcium Silicate and Sodium Fluoride, 451
Brotherton, Charles · Gift of £55,000 to the University of Leeds for a new chemical engineering laboratory, 659
Brown, F. : Awarded a Shirley Fellowship by the British Cotton Industry Research Association, 686
Brown, F., and others : Application of New Methods of End-Group Determination to Structural Problems in the Polysaccharides, 785
Brown, Robert · Degree of D.Sc. in the University of London conferred on, 533
Brown, R. L. : Strength of Materials, 307
Brown, R. L., and Hawksley, P. G. W. : Packing of Regular (Spherical) and Irregular Particles, 421
Brown, Prof. R. N. Rudmose : Retirement from the chair of geography at the University of Sheffield, 106 ; work of, 106
  United States Antarctic Discoveries, 399

Engineers' Study Group on Economics : Annual General Meeting, 686
Engineers (Chemical), Institution of, the Institute of Physics and the Chemical Engineering Group of the Society of Chemical Industry : Joint conference on Instruments for the Automatic Controlling and Recording of Chemical and other Processes, 45, 723
Engineers (Civil), Institution of : Field-Marshal the Hon. Sir Harold Alexander and Sir Edward Appleton elected honorary members, 598
Engineers (Electrical), Institution of . Award of Premiums, 17
  Election of officers, 108
  Annual Report for the Year 1944–45, 139
English, H., and others : Use of Carbon Dioxide in Fruit Storage and Transport, 178
Ennis, C. C., and others : Observations and Results in Physical Oceanography, 341
Epstein, Dr. M (edited by) : The Annual Register for the Year 1944, *review*, 489
  The Statesman's Year Book for 1945, *review*, 614
Esben-Petersen, Peter : *Death* of, 415
Esdaile, Dr. Arundell · Microfilm and other Means of Documentary Reproduction, 26
'Espinasse, Paul G. : Appointed lecturer and head of the Department of Zoology in the University College of Hull, 777
Euler, Prof. U. S. v. : A Sympathomometic Pressor Substance in Animal Organ Extracts, 18
Euler, Prof. U. S. v., and Östlund, E. : An Undialysable Pressor Principle in Organ Extracts, 49
Evans, Dr. A. G. : Friedel-Crafts Catalysts and Polymerization, 638
Evans, Dr. A. G., and Polanyi, Prof. M. : Low Temperature Polymerization, 638
Evans, Prof. C. Lovatt : A Great Physiologist, *review*, 764
Evans, Sir Geoffrey . *Obituary* of Prebendary Lonsdale Ragg, 289
Evans, Prof M. G · Appointed to the chair of chemistry in the University of Leeds, 386
  Energy Transfer in Chemical Reactions, 639
Evans, R. A. : Appointed a research assistant (biochemistry) in the Department of Animal Health at the University College of Wales, Aberystwyth, 331
Evans, Dr. U R. (Rideal, Prof E. K., and) : *Obituary* of Prof. Leif Tronstad, 74
Evans, Dr. W. C. : Appointed special lecturer in biochemistry in the Department of Animal Health at the University College of Wales, Aberystwyth, 331
Eve, A. S., and Creasey, C. H. : Life and Work of John Tyndall, *review* by Lord Rayleigh, 189
Ewer, Dr. D. W. : Acoustic Control in the Flight of Bats, 692
Exploration of the Sea, International Council for the : Reconstitution of the, 597

FAHRENHORST, Eberhard (Bulian, Walter, and) · Metallography of Magnesium and its Alloys, translated by the Technical Staffs of F. A. Hughes and Co , Ltd., and Magnesium Elektron, Ltd., *review*, 614
Fairbrother, Dr. F. : The Catalytic Halides, 638
Fairburn, C. E. : *Death* of, 596
Fairburn, W. A. : Appointed conservator of forests, Nigeria, 687
Fairweather, Dr. Alan : Closure and Partial Separation of a Metallic Contact, 545

Faraday, Dr. Joseph E. : Encyclopedia of Hydrocarbon Compounds, Replacement-addition issue of C_1 to C_8, 744
Farber, Prof. Marvin : The Foundation of Phenomenology—Edmund Husserl and the Quest for a Rigorous Science of Philosophy, *review* by F. Ian G. Rawlins, 516
Farmer, Dr. E H. . Oxidative Breakdown of Rubber, 10
Farrington, A : Lowering of Sea-Level in Glacial Times, 396
Fawcett, G. S : *Death* of, 596
Fazal-Uddin (Madhok, Dr. M R., and) : Losses of Nitrous Nitrogen from Soils on Desiccation, 49
Feather, Prof. Norman . Appointed professor of natural philosophy in the University of Edinburgh, 415 ; work of, 415
  American Work on the Atomic Bomb Project, 768
Federation of British Industries : Appointment of B. J. A Bard as head of the F.B.I Research Secretariat and secretary of the F.B.I. Industrial Research Committee, 77
Federov, V K. Research on Conditioned Reflexes, 455
Feinberg, Dr. R : Units for Degree of Vacuum, 85
Ferguson, Prof. T. : Appointed a member of the Industrial Health Research Board of the Medical Research Council, 566
Fermor, Sir Lewis : *Obituary* of C. S. Middlemiss, 594
  Organisation of Scientific Research in the British Commonwealth, 758
Ferno, O (Deutsch, Dr A., and) : Use of Dibenzylphosphoryl Chloride for Phosphorylations, 604
Fersman, Prof. Alexander . *Obituary* by Prof. C E. Tilley, 12
  The Periodic Law and its Significance for Natural Science (*VOKS Bulletin* No. 6), 331
Fidler, D. N. : Appointed research assistant (animal husbandry) in the Department of Animal Health at the University College of Wales, Aberystwyth, 331
Field Studies Council, West of Scotland : Inauguration of the, 331
Fiennes, R. N. T.-W- . A Sexual Reproduction Cycle of *Trypanosoma congolense* Broden, 390
Fieser, Louis F., and Fieser, Mary : Organic Chemistry, *review* by Prof. John Read, 96
Finch, Prof G. I. : Some Comparisons between Universities, 184
  Visit to Belgium and Holland to convey the greetings of the Royal Society, 472
Fisher, Prof. R. A. : A New Test for 2 × 2 Tables, 388
Fishlock, C. W. L. : Appointed senior agricultural officer, Uganda, 445
Fishwick, V C. : Pigs, revised edition, *review* by Dr. John Hammond, 434
FitzGerald, O., and others : A Theory of the Formation of Hydrochloric Acid in the Gastric Mucosa, 477
Fitzgerald, Prof W. : A Plan for Decentralizing Administration in Germany, *review*, 253
  The Geographer as Humanist, 355
Fleming, Sir Alexander : Appointed a member of the Medical Research Council, 362
  Awarded the Moxon Medal of the Royal College of Physicians, 531
  Nobel Prize for Medicine for 1945 awarded jointly to Sir Howard Florey, Dr E. B. Chain and, 533, 564
Fleming, Dr. John A. : Awarded the third Charles Chree Medal and Prize of the Physical Society, 658 ; work of, 658
Fleming, Dr J. A , and others : Observations and Results in Physical Oceanography, 341
Flemmich, C. O , and others : Need for Development of Tropical Ecological Studies, 627
Florey, Sir Howard : Nobel Prize for Medicine for 1945 awarded jointly to Sir Alexander Fleming, Dr. E. B. Chain and, 533, 564
Florkin, Prof. Marcel : Léon Fredericq et les débuts de la physiologie en Belgique, *review* by Prof. C. Lovatt Evans, 764
Flower, Newman : Through my Garden Gate, *review*, 614
Flugel, Dr. J. C. : The Scapegoat in Modern Europe, 380
Foggie, A. : Appointed senior assistant conservator of forests, Nigeria, 264
Foister, Dr. C. F , and others : Control of Dry Rot of Seed Potatoes by Dusting, 394
Foley, E J , and others : 'Fissibactericidal' Nature of Penicillin Action, 49
Folley, Dr. S. J. (Cowie, A T., and) : Parathyroidectomy and Lactation in the Rat, 719
Forde, Prof. C Daryll : Appointed to the University of London chair of anthropology at University College, 76
Forrest, J. S : The Corrosion of Metals, 438
Forrester, Lord : Appointed a member of the Industrial Health Research Board of the Medical Research Council, 566
Forrester, W F., and Hinde, R. M. : Crystal Structure of Barium Titanate, 177
Forster, Sir Martin : *Obituary* by Prof. J. L. Simonsen, 13
Forsyth, G. H. . Appointed to the chair of mechanical and marine engineering at King's College, Newcastle-upon-Tyne, 140
Forsyth, Dr. J. S Appointed Brotherton lecturer in chemical engineering at the University of Leeds, 659
Foster, Dr. Maunder . Strength of Materials, 307
Fowler, Henry B Description of a New Genus and Species of Apogonid Fish from New Jersey, 395
Fox, Sir Cyril : A Find of the Early Iron Age from Llyn Cerrig Bach, Anglesey, 309
Fox, Prof. H Munro . Individual Hæmoglobins, 18
  Appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 473
  Hæmoglobin in Blood-sucking Parasites, 475
Fraenkel, Prof. W. H. *Obituary* by E Scheuer, 773
Franklin Institute : Reports of the Biochemical Research Foundation, 331
Fredericq (Léon) et les débuts de la physiologie en Belgique (Prof. Marcel Florkin), *review* by Prof. C Lovatt Evans, 764
Freedom in Science, Society for . Occasional Pamphlet No. 1, Is the Progress of Science Controlled by the Material Wants of Man? (Dr. F. Sherwood Taylor), 166
French Association for the Advancement of Science : Congrès de la Victoire, 532
Fréon, A. : Cosmic Rays, 543
Freudenthal, Dr. Walter . Appointed to the University of London readership in dermatological histology at University College Hospital Medical School, 714
Friedenwald, Prof. Harry : The Jews and Medicine, *review* by Dr. Walter Pagel, 31
Friedmann, Dr. E. (Laser, Dr H., and) . Crystalline Hæmolytic Substance from Normal Blood, 507
Frilley, M Cosmic Rays, 544
Fritsch, Prof. F E. : Ceratium and Marine Hydrography, 181
Fuel, Institute of : Elections, 45
  Appointment of R. W. Reynolds-Davies as deputy secretary, 329
Fulton, J D : Penicillin in Leishmania Infections, 203
Furth, Dr. R., and others : A Photo-Electric Fourier Transformer, 756

GADDUM, Prof. J. H. : Lognormal Distributions, 463, 747
  Obituary of Prof. Velyien Henderson, 683
Gage, Prof George R. : *Death* of, 471
Gagnon, Dr Paul : Appointed a member of the National Research Council of Canada, 416
Gale, Miss M R. : Some Comparisons between Universities, 184
Galotchkina, L. P. (Kravkov, Prof. S V , and) Electrotonus in Colour Vision, *erratum*, 626
Gardiner, Prof. J Stanley : *Obituary* of Dr. L. A Borradaile, 622
Gardner, R (Bryant, L R , and) . Phosphorus Deficiency of Fruit Trees, 178
Garnier, Dr Georges : Cervico-Facial Pigmentation (Melanosis of Riehl-Poikiloderma), translated by Major James Marshall, 163
  Relation of the Gonadal Hormones to certain Dermatoses, translated by Major James Marshall, 163
Garrick, F. J. . Time, Number and the Atom (R. Fortescue Pickard), *review*, 489
Garrod, Prof. L. P : Visit to Belgium to lecture on Penicillin, 533
Gas Light and Coke Company : To broaden its research programme, 202
Gas Research Board : Fifth Annual Report, 370 ; *erratum*, 387
Gause, Prof G. F : Properties of Optically Isomeric Mepacrines, 784
Gauzit, J , and others Infra-Red Spectrum of the Night Sky, 114
Gaviola, Enrique : What are Comets?, 79
Gayler, Dr. M L. V. . Striated Structure of Age-hardened Alloys, 333
Geddes, Patrick (Philip Boardman), *review* by R. Brightman, 612 ; *erratum*, 687
Genetical Society : Election of officers, 202
  Special meetings, 473
Geographical Society, Royal : Exhibition of German Military Maps, 445
  Appointment of Lieut -Colonel L. P. Kirwan as secretary, 445
  Christmas Lectures, 714
Geological Society of London : Fund to defray the costs of an instructional tour for students, 533
Geological Survey of Great Britain : Appointment of Dr. W. F. P. McLintock as director, 168, 329
Geological Survey (Scottish Office) : Retirement of Dr. Murray Macgregor, 743
  Appointment of T. H Whitehead as director, 743
Gerhardt, F , and others : Use of Carbon Dioxide in Fruit Storage and Transport, 178
Ghosh, Sir J. C , and Sastry, S. L. : Chromium Oxide as a Promoter in Catalysts for the Fischer-Tropsch Synthesis, 506
Ghosh, S K , and Das Gupta, N. N : Energy Spectrum of Mesotrons at Low Energies, 83
Giffen, Dr. Edmund . Appointed to the chair of civil and mechanical engineering at Queen Mary College, London, 137 ; work of, 137
Gilbert, P T. : The Corrosion of Metals, 437
Gilbert, jr., Wm H. : Peoples of India, 292
Gillespie, Dr R. D. : *Death* of, 596
Gillman, Dr. J., and others : Porphyrin Fluorescence in the Livers of Pellagrins in relation to Ultra-Violet Light, 689
Glaxo Laboratories, Ltd. : Demonstration of the preparation of Penicillin, 386
Gleissberg, Dr. W. : A Forecast of Solar Activity, 539
Glock, Dr. Gertrude E. : Thiourea and the Suprarenal Cortex, 508
Gluckauf, Dr. E. . Chromatography of Two Solutes, 205, 571
  Adsorption Isotherms from Chromatographic Measurements, 748
Godsil, H C., and Byers, Robert D. : A Systematic Study of the Pacific Tunas, 184
Godwin, Dr. H : Hay-fever Plants, *review*, 317
  Archives of the Lakes, 383
Golberg, Dr Leon, and others : B Vitamins in African Fermented Foods, 364
González, Dr. Gastón, and others . Fluorescence Microscopy of Tubercle Bacilli, 16
Goodeve, Dr. C. F. : Appointed director of the British Iron and Steel Research Association, 138, 472
  Retirement from the post of deputy controller for research and development in the Admiralty, 472
Goodey, Dr. T. : Calomel and Onion Eelworm, 393
Goodlet, Commander B. L. : Elected a fellow of the Royal Society of South Africa, 687
Goodliffe, Frank : The Film in Science, 426
Goodwin, Dr. E. T. . Resignation from the lectureship in mathematics in the University of Sheffield, 473
Goodwin, L G. : Oedema in Hamsters Inected with *Leishmania*, 476
Gordon, Dr. C. : Organisation of Scientific Research in the British Commonwealth, 758
Gordon, Seton : A Highland Year, *review* by Dr. F. Fraser Darling, 219
Gore, Robert C., and others . Infra-red Spectroscopy, *review* by Dr. H. W. Thompson, 65
Gottschalk, Dr A. . Yeast Hexokinase and its Substrates *d*-Fructofuranose and *d*-Glucose, 540
Gough, Dr. H. J. . Released by the Ministry of Supply, 168
  Appointed engineer-in-chief of Lever and Unilever, Ltd., 202, 290 ; work of, 290
Gough, V. E. (Powell, E. F., and) : The Mechanism of Rubber Cracking, 11
Graham, Edward H. : Natural Principles of Land Use, *review* by Sir John Russell, 675
Graham, H. W., and Bronikovsky, N The Genus *Ceratium* in the Pacific and North Atlantic Oceans, 181
Graham, H. W., and Moberg, Erik G. : Chemical Results of the last Cruise of the *Carnegie*, 341
Grape, Dr. Anders . A Recently Discovered Manuscript by Linnæus, 351

Grassland Improvement Station : Sir George Stapledon to retire from the directorship, 598
Grassland Society, British First meeting of the, 78
Gray, Elizabeth G., and others : Blind Seed Disease of Rye-Grass, 178
Gray, Prof J. A. : Reappointed a member of the National Research Council of Canada, 416
Gray (Thomas) Memorial Trust : Prize and Award under the, 17
Grayson, Miss Dorothy : The Science Film in Education, 426
Greaves, E. G. N. Appointed deputy Government chemist, Trinidad, 687
Green, A. A. (Parkin, E. A, and) : Toxicity of D D T. to the Housefly, 745
Green, Dr. H. L. H. H : *Obituary* of Prof. J. T. Wilson, 772
Green, Prof H. N. (Bielschowsky, F., and) : An Induced Carcinoma in the Fowl, 780
Green, Prof. H. N. (Bielschowsky, Márian, and) : Synthesis of Adenosine Triphosphate by an Enzyme System of Ischæmic Muscle, 117
Greenstein, Dr. J. P. : Mammary Tumours in Mice, 787
Greenwood, Prof. Major : Retirement from the University of London chair of epidemiology and vital statistics at the London School of Hygiene and Tropical Medicine, 43
Gregory, J N, and others : Lubrication of Metal Surfaces by Fatty Acids, 97
Gregory, Sir Richard : Tribute to the influence of the Imperial College of Science and Technology, 519
Greig, Dr James : Appointed to the University of London chair of electrical engineering at King's College, 660
Gresford, Guy B . The Scientist and the Economic and Social Council, 625
Greville, Dr G D : Biochemical Aspects of Mental Disorder, 101
Grew, K. E. : Effect of Pressure on Thermal Diffusion in Gases, 267
Griffith, A L., and others : Need for Development of Tropical Ecological Studies, 627
Grimes, W. F. : Appointed keeper and secretary of the London Museum, 660
Grinnell, Joseph, and Miller, Alden H. . The Distribution of the Birds of California, *review*, 34
Grunberg, L., and Nissan, Dr A. H. . Viscosity of Ordinary Liquids at High Rates of Shear, 241
  Degree of Association of Water from the Energy of Viscosity and the Work of Cohesion, 335
Grzybowski, S . Some Comparisons between Universities, 183
Gudger, Dr E W : Completion of the Bashford Dean Memorial Volume on Archaic Fishes, 533
Guha, B S., and others (edited by) : Essays in Anthropology Presented to Rai Bahadur Sarat Chandra Roy, *review* by Prof. J. H Hutton, 66
Gunn, Dr D. L, and others . Mass Departure of Locust Swarms in relation to Temperature, 628
Gurney, C. : Strength of Materials, 306
Gurney, Dr. O. R. . Appointed Shillito reader in assyriology in the University of Oxford, 140
Gutenberg, B., and Richter, C. F. : Frequency of Earthquakes in California, 371

HACKETT, Wing-Comdr C J. : Appointed director of the Wellcome Museum of Medical Science, 416
Hadingham, Squadron-Leader Ronald : Astronomical Air Navigation, second edition, *review*, 489
Hafez, Dr. M. : Bionomics of *Hylemyia cinerella* Fallen, 48
Hahn, Prof. Otto : Awarded the Nobel Prize for 1944 for Chemistry, 657 ; work of, 657
Hainsworth, C. H. . Retirement as lecturer in electrical engineering in the University of Sheffield, 79
Haïssinsky, M. : Anodic Deposit of Protactinium, 423
Halberstadt, E. S., and others : Univalent Electron Transfers in Aromatic Nitration?, 688
Haldane, Prof. J. B S : Cosmic Rays and Kinematical Relativity, 266
  Obituary of Miss E. R. Saunders, 385
Halnan, E. T. (Marshall, Dr. F. H. A, and) : Physiology of Farm Animals, third edition, *review* by Dr. John Hammond, 377
Halsall, T G : Awarded a Shirley Fellowship by the British Cotton Industry Research Association, 686
Halsall, T. G, and others : Application of New Methods of End-Group Determination to Structural Problems in the Polysaccharides, 785
Hamilton, S. B : Re-elected president of the Newcomen Society, 758
Hamilton, Prof. W J, and others : Human Embryology, *review* by Dr. D V. Davies, 315
Hammick, D. Ll., and Mason, S F. : Primary Degradation Products of Mepacrine in Human Urine, 718
Hammond, Dr. John : The Animal in Health, *review*, 377
  Science and Pig-keeping, *review*, 434
  Pig Production, 454
Handley, Dr W. R. : Appointed microbiologist in the Department of Forestry of the University of Oxford, 293
Hankey, Lord : Government Control in War, 457
Hannell, F. G Resignation as lecturer in geography in the University of Sheffield, 745
Hanson, Dr. Frank Blair : *Death* of, 199
Harding, D. W. : Appointed to the University of London chair of psychology at Bedford College, 108
Hardy, Prof. A. C. : Appointed Linacre professor of zoology and comparative anatomy in the University of Oxford, 108, 200 , work of, 200
Hardy, Prof. G H. : Work of, 76
Harkness, D. A E. : Appointed principal assistant secretary in charge of the Economics and Statistics Division of the Ministry of Agriculture and Fisheries, 687
Harland, Dr S. C., and Darlington, Dr. C D. *Obituary* of Prof. N I. Vavilov, 621
Harley, J L., and others : Need for Development of Tropical Ecological Studies, 627
Harris, Prof. John E. : Anomalous Inactivation of Heavy Metal Antifouling Paints, 206
Harris, J. R., and Hickey, Dr. M. D. : Occurrence of the Diphyllobothriidæ in Ireland, 447
Harris, Dr L. J., and Kodicek, Dr. E : The Vitamin B_2 Complex, 86
Harris, R. V. Degree of D.Sc. of the University of London conferred on, 108
Harrison, H C. : Weathering of GR-S, 10
Harrison, Dr. J V. . *Obituary* of Brigadier-General Sir Percy Sykes, 104
Harrison, R. W. F. : *Death* of, 106 ; *obituary* by Sir Henry Dale, 228
Hartridge, Prof H : Avoidance of Obstacles by Bats, 55
  An Illusion of Size, 118, 636
  Acoustic Control in the Flight of Bats, 490, 687, 692
  The Anti-Chromatic Reflex, 666
Hartshorn, Dr. L., and Wilson, W. : An Electrical Moisture Meter, 16
Hartwell, Dr. Gladys A. : Title of University of London reader in nutritional science conferred on, 566
Haslam, J. (Clark, L. M., and) : Occurrence of Boron Phosphate in Fireside Deposit from an Economizer, 302
Haurwitz, Prof. Bernhard, and Austin, Prof. James M. : Climatology, *review* by Prof. D Brunt, 157
Hawkins, Major T. H. : The Army School of Education, Eltham Palace, 527
  Timber Resources of Britain, *review*, 613

Hughes, Prof E. D. : To deliver the Tilden Lecture of the Chemical Society, 777
Hughes, Prof. E. D., and others : Univalent Electron Transfers in Aromatic Nitration?, 688
Hughes, Dr. L. E. C. : Operational Calculus, *review*, 6
  Waveform Analysis (R G. Manley), *review*, 765
Hulme, Dr. H. R. · Appointed scientific adviser to the Air Ministry, 745
Humason, M L. : Supernova in Canes, 777
Hunter, Dr A. : A New Cosmogony of the Solar System, 378
  A Physical Theory of the Solar Corona, 649
Hunter, Dr. D. : Appointed a member of the Industrial Health Research Board of the Medical Research Council, 566
Hunter-Smith, J. D : Appointed agricultural officer, Tanganyika, 687
Hurst, Dr. H : Enzyme Activity as a Factor in Insect Physiology and Toxicology, 194
Hurst, Dr J. E. : To be Sheriff of the City and County of Lichfield, 417
Hurwitz, Prof. Adolf : Vorlesungen uber allgemeine Funktionentheorie und elliptische Funktionen, dritte auflage, *review* by J. H. Pearce, 67
Husserl (Edmund) and the Quest for a Rigorous Science of Philosophy : The Foundation of Phenomenology—(Prof. Marvin Farber), *review* by F. Ian G. Rawlins, 516
Hutchinson, John · Common Wild Flowers, *review* by Prof. F. J. Lewis, 461
Hutton, Prof. J. H. : Symposium on India, *review*, 66
Hutton, Dr. R. S : Microfilm and other Means of Documentary Reproduction, 26
Huxley, Dr. Julian S. : Genetics and Major Evolutionary Change, *review*, 3
  Receipt of a letter from Prof. C. J. Van der Klaauw, 166
  Evolutionary Biology and related Subjects in the U.S.S.R., 254 ; *errata*, 293
  A United Nations Educational and Cultural Organisation—Science and the United Nations, 553
  Late Flowering of Horse-Chestnut, 574
  Letters received from Dr. N. Tinbergen, of Leyden, and Dr. A. Buzzati-Traverso, of Pallanza, 576
Hymas, F. C., and others : Efficacy of D.D.T. in Soap, 749

IMMS, Dr. A D. : Retirement from the readership in entomology in the Department of Zoology, Cambridge, 712 , work of, 712
Imperial Agricultural Bureaux . Joint Publication No. 7 on *Imperata cylindrica*, 342
Imperial Cancer Research Fund : Forty-second Annual Report for 1944–1945, 343
Imperial Chemical Industries, Ltd. : Fellowships at Cambridge, 17
  Offer to the University of Leeds to finance and support research on the behaviour of gases, 659
I.C.I. (India) : Offer to the National Institute of Sciences of India of 336,000 rupees for research fellowships in chemistry, physics and biology, 107
Imperial College of Science and Technology · Appointment of A. L. L. Baker to the University of London chair of concrete technology, 45
  Title of University of London reader in analytical chemistry conferred on L. S. Theobald, 566
  Appointment of Prof D. M. Newitt to the Courtaulds chair of chemical engineering, 714, 774
  Centenary celebrations of the, 264, 518
    Address by H.M. the King, 518
    Reply by Dr. R. V. Southwell, 519
    Tributes to the Influence of the Imperial College (Sir Richard Gregory), 519 ; (Dr. W. H. Eccles), 520 ; (Sir William Jarratt), 520
    Introductory Address (Lord Rayleigh), 520
  Contributions of the, to the Conquest of Disease (Lord Rayleigh), 520
  Physics and Astrophysics at the (Prof. Herbert Dingle), 562
  Engineering at the—The City and Guilds College (Prof. E. F. D. Witchell), 650
  The Royal School of Mines—Geology, Mining and Metallurgy at the (Prof. W. R. Jones), 706
Imperial Institute . Series of lectures on recent progress in Geological Investigation and Mineral Developments in the Colonies, 362
Imrie, Dr. C. Gray : Resignation as lecturer in physiology in the University of Sheffield, 79
Indian Statistical Institute : Work of the, 722
Industrial Health Research Board : Appointment of members by the Medical Research Board, 566
Infeld, Prof. L. : A New Approach to Relativistic Cosmology, 114
Ingelman, Bjorn, and Jullander, Ingvar · Preparation of Silicic Acid Jellies for Bacteriological Purposes, 572
Ingold, Prof. C. K. . Near Ultra-Violet Emission Bands of Benzene, 569
Ingold, Prof. C. K., and others : Univalent Electron Transfers in Aromatic Nitration?, 688
Innes (John) Horticultural Institution : To move from Merton to Bayfordbury, 586
  Thirty-fifth Annual Report, 669
Innes, Roy : Appointed general secretary of the Association of Scientific Workers, 331
Institute of Fuel · Elections, 45
  Appointment of R. W. Reynolds-Davies as deputy secretary, 329
Institute of Metals, the Iron and Steel Institute and the Institution of Mining and Metallurgy : To establish, in co-operation with the Ministry of Education, a scheme for National Certificates in Metallurgy, 138
Institute of Physics (London and Home Counties' Branch) : Discussion on the Corrosion of Metals, 435
Institute of Physics, the Institution of Chemical Engineers, and the Chemical Engineering Group of the Society of Chemical Industry Joint conference on Instruments for the Automatic Controlling and Recording of Chemical and other Processes, 45, 723
Institute for the Study of Animal Behaviour : Election of officers, 566
Institute of Welding : Sir William J. Larke Medal for 1945 awarded to W. K. B. Marshall, 473
  Prize awards, 473
Institution of Chemical Engineers, the Institute of Physics and the Chemical Engineering Group of the Society of Chemical Industry : Joint conference on Instruments for the Automatic Controlling and Recording of Chemical and other Processes, 45, 723
Institution of Civil Engineers : Field-Marshal the Hon. Sir Harold Alexander and Sir Edward Appleton elected honorary members, 598
Institution of Electrical Engineers : Award of Premiums, 17
  Election of officers, 108
  Annual Report for the Year 1944–45, 139
Institution of Metallurgists : Inaugural Meeting of the, 710
Institution of Mining and Metallurgy, the Institute of Metals and the Iron and Steel Institute : To establish, in co-operation with the Ministry of Education, a scheme for National Certificates in Metallurgy, 138
Institution of Naval Architects . Appointment of Capt. Arthur Dyce Duckworth as secretary, 502
Institution of the Rubber Industry (Midland Section of the) : Symposium on the Physical and Chemical Breakdown of Rubber, 9
International Council for the Exploration of the Sea : Reconstitution of the, 597
International Wool Secretariat · Grant of £300 a year to the University of Leeds for the establishment of a Wool Research Scholarship, 502
Iron and Steel Institute, the Institution of Mining and Metallurgy and the Institute of Metals : To establish, in co-operation with the Ministry of Education, a scheme for National Certificates in Metallurgy, 138
Iron and Steel Research Association, British : Formation of the, 138
  Appointment of Dr. C F. Goodeve as director, 138, 472
Irving, Prof. J. T. : Effect of Restriction of Food Intake upon the Incisor Teeth of Rachitic Rats, 664
Irwin, Raymond : Appointed director of the School of Librarianship at University College, London, 108, 202

JACKS, G. V. : Soil Erosion in New Zealand, *review*, 703
Jackson, Prof. Willis, and Reddish, W. : High Permittivity Crystalline Aggregates, 717
Jacobs, Dr. Morris B. : The Chemistry and Technology of Food and Food Products, Vol. 2, *review* by Dr. T. Moran, 220
Jacoby, Dr. F. : Differentiation between Eosinophils and Pseudo-eosinophils of Rabbits' Blood by means of a Peroxidase Reaction, 420
James, Dr. Sybil P., and others : A Constitutional Synthesis of Chondrosamine, 308
Jánossy, Dr. L. : Cosmic Rays, 543
  Cosmic Radiation, 704
Jarratt, Sir William : Tribute to the influence of the Imperial College of Science and Technology, 520
Jefferies, Richard : The Wood from the Trees, *review* by Major T. H. Hawkins, 613
Jefferson, G. T. : Heat Injury in Insects, 111
Jefferson's (Thomas) Garden Book, 1766–1824, with Relevant Extracts from his other Writings (annotated by Prof. Edwin Morris Betts), *review* by Dr. E. J. Salisbury, 128
Jeffery, Prof. G. B · Appointed director of the Institute of Education, University of London, 443 ; work of, 443
Jeffrey, Dr. G. A. : Structure of Dibenzyl, 82
Jennings, M A. . Activity of Helvolic Acid against *Mycobacterium tuberculosis*, 633
Joffe, Prof. A., and others : *Obituary* of Prof. L. I. Mandelstam, 105
Johannsen, —. : Atomic Weight of Beryllium, 179
Johnson, Dr. P. : Elected to an Imperial Chemical Industries Fellowship at Cambridge, 17
  Comparison of Enzyme and Immune Reactions, *review*, 517
Joliot-Curie, Mme. . Cosmic Rays, 544
Jones, Dr. Ernest : The Scapegoat in Modern Europe, 381

Marine Biological Association . Appointment of F. S Russell as director of the Laboratory at Plymouth, 76
Marine Biological Association, Scottish : Annual Reports for 1938–39 to 1943–44, 668
Markwick, A. H. D : Particle Shape, 177
Marlio, Dr. Louis (Moulton, Dr. Harold G., and) : The Control of Germany and Japan, 64
Marshall, C. F. Dendy : *Death* of, 471
Marshall, C W. : Electricity Supply Organisation, *review*, 585
Marshall, Dr. F. H A , and Halnan, E. T . Physiology of Farm Animals, third edition, *review* by Dr. John Hammond, 377
Marshall, Major James . Cervico-Facial Pigmentation (Melanosis of Riehl-Poikiloderma), (Dr. Georges Garnier), *translation*, 163 .
  Relation of the Gonadal Hormones to certain Dermatoses (Dr. Georges Garner), *translation*, 339
  Deficiency Diseases in Belgium, *review*, 551
  Penicillin in the Treatment of Syphilis, 769
Marshall, John F. : Records of *Culex* (*Barraudius*) *modestus* Ficalbi (Diptera, Culicidæ) obtained in the South of England, 172
Marshall, P. B. : Loss of Antimalarial Properties in Quinine Degradation Products, 505
Marshall, W. K. B. : Awarded the Sir William J. Larke Medal of the Institute of Welding for 1945, and a first prize of £50, 473
Martin, H , and Wain, R. L. . Phytopathological Uses of the new Insecticide D D.T., 168
Mason, S E. (Hammick, D. Ll., and) : Primary Degradation Products of Mepacrine in Human Urines, 718
Maxcy, Dr. Kenneth F. : Awarded the United States Typhus Commission Medal, 445
Maxwell, Margaret, and others : Fundamental Investigations on the Fellmongering Process, 483
May, W. E : Repeating Compasses, 593
Mayer, Dr Fritz . The Chemistry of Natural Colouring Matters, translated and revised by Dr A. H Cook, *review* by Prof W. Baker, 552
Maze, M. : Cosmic Rays, 543
Medical Academy of the U S.S.R. : Election of first members, 714
Medical Association, British (Nutritional Committee of the Jamaica Branch) : Report on Nutrition and Agriculture In Jamaica (Dr. W. E. McCulloch and colleagues), 288
Medical Research, Committee on (Washington), and the Medical Research Council (London) : Chemistry of Penicillin, 766
Medical Research Council : Resumption of Rockefeller Medical Fellowships, 17
  Report on Health Research in Industry, 148
  War-time Memorandum on Nutritive Values of War-time Foods, 330
  War Memorandum No. 13, Arterial *Injuries*, 362
  Appointment of Prof. P A. Buxton and Sir Alexander Fleming as members, 362
  Appointment of members to the Industrial Health Research Board, 566
Medical Research Council (London), and the Committee on Medical Research (Washington) : Chemistry of Penicillin, 766
Medicine, Royal Society of (Psychiatry Section) : Meeting on the Biochemistry of Mental Disorder, 101
Medicine, Royal Society of, in co-operation with the Scientific Film Association : To prepare a catalogue of Medical Films in Great Britain, 387
Meek, Dr. J. M., and Waterton, F. W. : Measurement of High Voltages, 422
Meek, Dr J. M. (Craggs, Dr. J. D., and) . Afterglow Effects in High-Pressure Gases, 21
Mehta, G. K., and others : Splitting of the Sodium Doublet Lines, 662
Mellanby, Dr. Kenneth : Appointed to the University of London readership in entomology at the London School of Hygiene and Tropical Medicine, 712
Mellon Institute of Industrial Research : Thirty-second Annual Report, 541
Melville, Prof. H W. : The Mechanism of Polymerization of Vinyl Compounds, 639
Melville, Prof H. W. (Burnett, G. M , and) Propagation and Termination Coefficients for Vinyl Acetate Photopolymerization, 661
Mendeléeff : Tribute to, in connexion with the seventy-fifth anniversary of the discovery of the Periodic Law (M. Pervukhim), 331
Menkart, J., and Speakman, Prof J. B : Scaliness of Wool Fibres, 143
Menzies, A. (Stoy, R. H., and) : Re-Observation of the Magnitudes of the Southern Comparison Stars for Eros, 179
Menzies, Group-Captain A. C. . Appointed controller of research and development to Adam Hilger, Ltd., 624
Merewether, Dr. E R. A. Appointed a member of the Industrial Health Research Board of the Medical Research Council, 566
Merriam, Dr. J C. : *Obituary* by Prof D. M. S Watson, 683
Merrill, Paul W. : Awarded the Henry Draper Medal for 1945 of the United States National Academy of Sciences, 575
Metallurgists, Institution of : Inaugural Meeting of the, 710
Metals, Institute of, the Iron and Steel Institute and the Institution of Mining and Metallurgy : To establish, in co-operation with the Ministry of Education, a scheme for National Certificates in Metallurgy, 138
Meyer, Dr Gustave M. : *Death* of, 199
Meyer, Prof. Martin : The Science of Explosives, *review* by Prof John Read, 5
Middlemiss, C. S. : *Obituary* by Sir Lewis Fermor, 594
Miles, Capt. J. A. R. : Antigens and Antibodies, *review*, 348
Miller, Alden H. (Grinnell, Joseph, and) . The Distribution of the Birds of California, *review*, 34
Miller, Neal E., and Dollard, John : Social Learning and Imitation, *review* by Dr. John Cohen, 515
Millport Marine Laboratory : Research Work at the, 668

Mills, J. P., and others (edited by): Essays in Anthropology Presented to Rai Bahadur Sarat Chandra Roy, *review* by Prof. J. H. Hutton, 66
Milne, Prof. E. A.: Kinematical Relativity, 747
Milne-Thomson, Prof. L. M: Bessel Functions, *review*, 190
Milne-Watson, Sir David: *Death* of, 443; *obituary* by Dr. E. F. Armstrong, 499
Milsom, F.: *Death* of, 742
Mines, Royal School of—Geology, Mining and Metallurgy at the Imperial College (Prof. W. R. Jones), 706
Mining and Metallurgy, Institution of, the Institute of Metals and the Iron and Steel Institute: To establish, in co-operation with the Ministry of Education, a scheme for National Certificates in Metallurgy, 138
Ministry of Agriculture and Fisheries: Advisory Leaflet No. 315 on Weed Control in Cereals, 330
  Retirement of Dr E. S. Russell from the post of director of fishery investigations, 687
  Appointment of R. R. Enfield as chief economic adviser, 687
  Appointment of D A. E. Harkness as principal assistant secretary in charge of the Economics and Statistics Division, 687
Ministry of Education: Report on Higher Technological Education, 699
Ministry of Education (Iron and Steel Institute, the Institution of Mining and Metallurgy and the Institute of Metals, in co-operation with the): To establish a scheme for National Certificates in Metallurgy, 138
Ministry of Labour and National Service: Technical and Scientific Register of the, 502
Ministry of Supply: Release of Dr H. J. Gough, 168
  Appointment of Prof. J. E. Lennard-Jones as chief scientific officer, 168
Ministry of Town and Country Planning. National Maps of Britain, 776
Minkoff, G. J., and others: Univalent Electron Transfers in Aromatic Nitration I, 688
Minorsky, Prof. V.: *Obituary* of Brigadier-General Sir Percy Sykes, 104
Mirsky, L.: Appointed assistant lecturer in mathematics in the University of Sheffield, 473
Mitchell, Dr. C. Ainsworth: Retirement from the editorship of *The Analyst*, 443; work of, 443
Mitchell, Sir Peter Chalmers: *Death* of, 15; *obituary* by Dr. Edward Hindle, 103
Mitchell, R. L. (Wager, Prof. L. R., and): Distribution of Vanadium, Chromium, Cobalt and Nickel in Eruptive Rocks, 207
Mitrany, Prof. David: Method in Social Studies, *review*, 278
Moberg, Erik G. (Graham, Herbert W., and). Chemical Results of the last Cruise of the *Carnegie*, 341
Moholy, Mrs. L.: Microfilm and other Means of Documentary Reproduction, 24
Mohr, Prof. Dr. E. C. Jul.: The Soils of Equatorial Regions, with special reference to the Netherlands' East Indies, translated from the Nederlandsch by Robert L. Pendleton, *review* by Dr. A. Muir, 93
Mommaerts, Dr. W. F. H. M.: Molecular Morphology of Myosin, 631
Mommaerts, Dr. W. F. H. M. (Laki, Dr K., and): Transition of Fibrinogen to Fibrin as a Two-Step Reaction, 664
Moncrieff, Dr. Alan. Appointed to the Nuffield chair of child health at the University of London Institute of Child Health, 714
Moore, Prof. E. S.: Elected president of the Royal Society of Canada for 1945–46, 272
Moore, P. T. (Conway, Prof E. J., and). Cation and Anion Permeability Constants for the Muscle Fibre Membrane, 170
  Rate of Entrance of Ammonia into Muscle Fibres in relation to Carbon Dioxide Tension, 270
Moore, W. C.: Cereal Diseases, 533
Moran, Dr. T.: Food Science, *review*, 220
More, Prof. J. A.: *Obituary* of Prof. Ernest Shearer, 470
Morgan, Dr. A. E.: Appointed educational director of the British Council, 77
Morgan, Dr. W. T. J., and others: Enhancement of the Action of Immune Hæm-Agglutinins by Human Serum, 663
Morris, C. J. O. R. (Hoch, H., and): Heterogeneity of Human Serum Albumin, 234
Morris, Dr. H. P.: Mammary Tumours in Mice, 787
Morris, Phillip: Appointed vice-chancellor of the University of Bristol, 659; work of, 659
Morrison, Herbert. Government Support for Research Associations in Britain, 597
Mossman, Prof. H. W., and others: Human Embryology, *review* by Dr. D. V. Davies, 315
Mott, Prof. N. F.: Cosmic Rays, 543
Mottram, Dr J. C.: *Death* of, 443
Mottram, Prof. V. H.. The Physical Basis of Personality, *review* by Dr. G. Lapage, 763
Motz, Dr. H.: Appointed lecturer in engineering physics in the University of Sheffield, 79
Moulton, Dr. Harold G., and Marlio, Dr. Louis: The Control of Germany and Japan, 64
Muir, Dr. A.: Tropical Pedology, *review*, 93
  Pedology in the U.S.S.R., 258
Munroe, Helen: Classified List of Smithsonian Publications Available for Distribution, 362

Opie, Prof. Eugene L. : Awarded the Weber-Parkes Prize and Medal of the Royal College of Physicians, 531
Oram, A. T : A Theory of Telepathy, 303
Orowan, Dr. E. : Grant from the Nuffield Foundation for a special research fellowship, 202
  Strength of Materials, 307
Orr, Sir John Boyd : If I were Minister of Food in Peace-time, 292
  Elected rector of the University of Glasgow, 502
  Appointed the first director-general of the United Nations Food and Agricultural Organisation, 533
Orr, Dr. W. J. C., and Bolland, J. L : Thermal Breakdown of Rubber, 9
Orton, Prof J. H. : Utilization of the Slipper-Limpet (*Crepidula fornicata*) as Food as an Aid to the Recovery of Oyster-Culture in the Thames Estuary, 665
Orwin, Dr C S. : Retirement from the Agricultural Economics Research Institute, Oxford, 500
Östland, E. (Euler, Prof U. S. v, and): An Undialysable Pressor Principle in Organ Extracts, 49
Ottaway, Christopher W. : Awarded a senior Wellcome Fellowship for Veterinary Research, 45
Ottesen, J. (Hevesy, Prof. G., and) : Life-Cycle of the Red Corpuscles of the Hen, 534
Owen, Archdeacon (Leakey, Dr. J. B. S, and) : A Contribution to the Study of the Tumbian Culture in East Africa, 371

PADGWICK, G. W : Degree of D Sc. of the University of London conferred on, 108
Padhye, M. R (Asundi, Prof. R. K, and) : Near Ultra-Violet Emission Bands of Benzene, 368
Pagel, Dr. Walter : Jewish Physicians through History, *review*, 31
Paget, Sir Richard : Is Human Speech Good Enough ?, 209
Pais, Dr. A. : Life-time of the Neutral Meson, 715
Palæontographical Society : Publication of a Directory of British Fossiliferous Localities, 168
Palin, D. E., and Powell, H. M. : Hydrogen Bond Linking of Quinol Molecules, 334
Parker, Audrey M. B : Unit Cell and Space-Group of Co_2-Al_9, 783
Parkin, E. A., and Green, A. A. : Toxicity of D D.T. to the Housefly, 745
Parkinson, Dr. D., and Bloxham, J L. : The Behaviour of Natural Rubber and GR-S under Repeated Stress Cycles, 11
Parks Committee, National : Appointed by the Minister of Town and Country Planning, 108
Parshad, R. : Measurement of Ultrasonic Velocities in Extended Solids, 637
Parson, Alfred Lauck : Stability of the Earth's Atmospheric Oxygen, 504
Patchin, George : Retirement from the principalship of the Sir John Cass Technical Institute, 445
Paterson, Dr. C. C. : Appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 473
Patil, B. S., and others : Splitting of the Sodium Doublet Lines, 662
Paul, R. H. : Long Transmission-line Problems, 179
Pauli, Prof. Wolfgang : Awarded the Nobel Prize for Physics for 1945, 657 ; work of, 657
Pavlova, V. I. : Research on Conditioned Reflexes, 455
Pearce, Dr. J. A. : Presidential Address to Section III of the Royal Society of Canada, 271
Pearce, J. H. : Potential Theory, *review*, 5
  Functions of a Complex Variable, *review*, 67
Pearce, S. C. : Lognormal Distributions, 747
Peatt, Brigadier E. S. W. : British Army Veterinary Services in the Far East, 60
Peddie, Prof. W. : The Fitzgerald Contraction as the Origin of our Experience of Time and its Lapse Rate, 336
Pedersen, Dr. Kai O. : Ultracentrifugal Studies on Serum and Serum Fractions, 247
Peklo, Dr. J. : Papers on the Genetics of certain Fungi and the Problem of 'Relative Sexuality' among lower Plants, 416
Pelseneer, Dr. P. : *Obituary* by R. Winckworth, 136
Pendlebury, H. M. : *Death* of, 443
Pentzer, W. T., and others : Use of Carbon Dioxide in Fruit Storage and Transport, 178
Percival, Dr. E. G. V. (Dewar, Eric T., and) : A Polysaccharide from *Gigartina stellata*—the Isolation of Crystalline 2 : 6-Dimethyl-*β*-*d*-Galactopyranose from the Methylated Polysaccharide, 633
Perry, Flying-Officer F. C., and others : Mass Departure of Locust Swarms in relation to Temperature, 628
Perry, Stuart H. : Awarded the J. Lawrence Smith Medal for 1945 of the United States National Academy of Sciences, 575
Perutz, Dr M. F. : Elected to an Imperial Chemical Industries Fellowship at Cambridge, 17
Pervukhim, M. : Tribute to Mendeléeff in connexion with the seventy-fifth anniversary of the discovery of the Periodic Law (*VOKS Bulletin* No. 6), 331
Peters, N. : Die Bevölkerung des südatlantischen Ozeans mit Ceratien, 181
Peters, Prof. R. A. : The Vitamin B$_2$ Complex, 86
Peters, Prof. R. A, Stocken, Dr. L. A., and Thompson, Dr. R. H. S. : British Anti-Lewisite (*BAL*), 616
Pettersson, Prof. Hans : Swedish Oceanography during the War, 180
Pharmaceutical Society, College of the : Appointment of Dr. G. A H. Buttle to the University of London chair of pharmacology, 566, 624
Phelps, J. : An Illusion of Size, 269
Phillips, Major C. E. S. : *Obituary* by R. S. Whipple, 228
  Life and work to be commemorated at a meeting at the Royal Institution, 362
Phillips, R. : Appointed to undertake research in animal husbandry and the administration of investigational centres in the Department of Animal Health at the University College of Wales, Aberystwyth, 331
Phillis, Dr. E. : Appointed chief scientific officer, Department of Agriculture, Trinidad, 687
Philpot, A. J. : Automatic Control and Recording in Chemical and other Processes, 723
Philpot, J. St. L. : Serum Proteins in the Ultracentrifuge, 247
Photographic Society, Royal (Scientific and Technical Group) : Series of lectures on How it Works in Photography, 293
Physical Society : Charles Chree Medal and Prize awarded to Dr. John A. Fleming, 658
  Awards, 685
  Exhibition of Scientific Instruments and Apparatus, 714
Physicians of London, Royal College of : Second Interim Report of the Social and Preventive Committee, 148
  Medal Awards, 531
Physics, Institute of (London and Home Counties' Branch) : Discussion on the Corrosion of Metals, 435
Physics, Institute of, the Institution of Chemical Engineers, and the Chemical Engineering Group of the Society of Chemical Industry : Joint conference on Instruments for the Automatic Controlling and Recording of Chemical and other Processes, 45, 723
Piaggio, Prof. H. T. H. : *Obituary* of Dr. A. Lees, 499
  Advanced Mathematics, *review*, 648
Pickard, R Fortescue : Time, Number and the Atom, *review* by F. J. Garrick, 489
Pickford, Dr R. W. : Darkened Violet in Colour Vision, 506

  Retirement of Dr. A D Imms from the readership in entomology, 712
  Appointment of Dr. V. B. Wigglesworth to the readership in entomology, 712
  Retirement of Prof. E. K Rideal as professor of colloid science, 714, 774
University of Durham : Appointment of G. H. Forsyth to the chair of mechanical and marine engineering at King's College, Newcastle-upon-Tyne, 140
  Appointment of Dr David H. Valentine to the readership in botany in the Durham Colleges, 140
  Appointment of Dr. A. C. Offord to the chair of mathematics in the Newcastle Division, 202
  Appointment of W. H. F. Barnes to the chair of philosophy in the Durham Division, 202
University of Edinburgh · The senior Hume Brown Prize in Scottish History awarded jointly to Dr. Alexander Clow and Mrs. Nan L. Clow, 45
  Appointment of Prof. Norman Feather as professor of natural philosophy, 415
University of Glasgow : Election of Sir John Boyd Orr as rector, 502
University of Leeds · Appointment of Dr. Irene Manton to the chair of botany, 108, 230
  Retirement of Prof. Robert W. Whytlaw-Gray from the chair of chemistry, 386
  Appointment of Prof. M. G Evans and Dr. E. G. Cox to the chairs of chemistry, 386
  Appointment of Dr. W. T Astbury to the chair of biomolecular structure, 501
  Title of emeritus professor conferred on Prof. R W. Whytlaw-Gray, 501
  Appointment of Wilfred Prest as visiting lecturer in the Department of Economics and Commerce, 501
  Annual grant of £600 from Turner and Newall, Ltd , for a research fellowship in engineering, chemistry, physics, textile industries or any allied science, 502, 659
  Grant of £10,000 from the Nuffield Trust to establish a readership or senior lectureship in the Dental School, 502
  Grant of £1,500 a year for two years from the Bradford Dyers' Association, Ltd , for two research fellowships, 502
  Grant of £300 a year from the International Wool Secretariat for a wool research scholarship, 502
  Grant of 6,500 dollars from the Rockefeller Foundation for the purchase of equipment in connexion with Prof. W. T. Astbury's researches, 502
  Annual grant of £100 from Williams (Hounslow), Ltd., for equipment in the Colour Chemistry and Dyeing Department, 502
  Grant of £750 from Babcock and Wilcox, Ltd., for equipment in the Coal Gas and Fuel Industries Department, 502
  Grant from the Leverhulme Trustees to enable Prof. Whytlaw-Gray to devote himself to research, 659
  Offer by the Imperial Chemical Industries, Ltd , to finance and support research on the behaviour of gases, 659
  Gift by Charles Brotherton of £55,000 for a new chemical engineering laboratory, 659
  Appointment of Dr. J S. Forsyth as Brotherton lecturer in chemical engineering, 659
University of London . Retirement of Prof. Major Greenwood from the chair of epidemiology and vital statistics at the London School of Hygiene and Tropical Medicine, 43
  Appointment of A. L. L. Baker to the chair of concrete technology at the Imperial College of Science and Technology, 45
  Appointment of Prof. C Daryll Forde to the chair of anthropology at University College, 76
  Appointment of Raymond Irwin to the directorship of the School of Librarianship at University College, 108, 202
  Title of reader in bacteriology in the University conferred on J. C. Cruickshank, 108
  Conferments of the degree of D.Sc., 108, 533
  Appointment of Dr. D. H Hey to the chair of chemistry at the Imperial College of Science and Technology, 108
  Appointment of Dr F. C. Benham to the chair of commerce at the London School of Economics, 108
  Appointment of D. W. Harding to the chair of psychology at Bedford College, 108
  Retirement of Prof. E. H. Lamb from the chair of civil and mechanical engineering at Queen Mary College, 137
  Appointment of Dr. Edmund Giffen to the chair of civil and mechanical engineering at Queen Mary College, 137
  Retirement of Prof L Bairstow from the Zaharoff chair of aeronautics, 165
  Appointment of Dr John Yudkin to the chair of physiology at King's College of Household and Social Science, 202, 471
  Appointment of Dr. L Dudley Stamp to the chair of geography at the London School of Economics and Political Science, 202, 291
  Retirement of Prof. Ll. Rodwell Jones from the chair of geography at the London School of Economics, 291
  Appointment of J Z Young to the chair of anatomy at University College, London, 415
  Appointment of Prof G B. Jeffery as director of the Institute of Education, 443
  Appointment of Prof. Harold Davenport to the Astor chair of mathematics at University College, 443
  Appointment of Prof. F. G. Young to the chair of biochemistry at University College, London, 471
  Appointment of Dr A I. Richards to the University readership in anthropology at the London School of Economics, 533
  Appointment of Dr. Margaret Read to the University readership in education at the Institute of Education, 533
  Appointment of Dr. James Henderson as academic registrar, 533
  Appointment of Colonel S J. Worsley as principal of the College of Estate Management, 533
  Appointment of Dr. G. A. H. Buttle to the chair of pharmacology at the College of the Pharmaceutical Society, 566
  Title of University professor of electrical engineering conferred on Dr H E. M. Barlow, 566
  Title of University reader in analytical chemistry conferred on L. S. Theobald, 566
  Title of University reader in nutritional science conferred on Dr. Gladys A. Hartwell, 566
  Appointment of Dr. James Greig to the University chair of electrical engineering at King's College, London, 660
  Appointment of Dr. Kenneth Mellanby to the readership in entomology at the London School of Hygiene and Tropical Medicine, 712
  Appointment of Dr. Karl Mannheim to the University chair of education at the Institute of Education, 714, 743
  Appointment of Dr. Walter Freudenthal to the University readership in dermatological histology at University College Hospital Medical School, 714
  Title of professor emeritus in morbid anatomy conferred on Prof. G W. de P. Nicholson, 714
  Appointment of Prof D M Newitt to the Courtaulds chair of chemical engineering at the Imperial College of Science and Technology, 714, 774
  Appointment of Dr. Alan Moncrieff to the Nuffield chair of child health at the Institute of Child Health, 714
University of London Institute of Child Health : Appointment of Dr. Alan Moncrieff to the Nuffield chair of child health, 714
University of London Institute of Education : Appointment of Dr. Margaret Read to the readership in education, 533
  Appointment of Dr. Karl Mannheim to the chair of education, 714, 743
University of Manchester (Department of Chemistry) : Conference on Friedel-Crafts Catalysts and Polymerization, 232
University of Oxford : Honorary degree of D.C.L conferred on Sir D'Arcy Thompson, 17, 43
  Osler Medal for 1945 awarded to Dr. C. G. Douglas, 17
  Honorary degree of D Sc. conferred on Prof. H. M. Turnbull, 108
  Appointment of Prof. A. C. Hardy to the Linacre chair of zoology and comparative anatomy, 108, 200
  Appointment of Dr. O. R. Gurney as Shillito reader in assyriology, 140
  Appointment of G. E. Blackman as Sibthorpian professor of rural economy, 262
  Appointments in the Department of Forestry, 293
  Appointment of Archibald N Black as Donald Pollock reader in engineering science, 417
University of Sheffield : Appointments, resignations and retirements, 79
  Two scholarships for a full-time degree course in mining to be provided by the Yorkshire Mine Workers' Association, 79
  Retirement of Prof. R. N. Rudmose Brown from the chair of geography, 106
  Appointment of Squadron-Leader David L. Linton to the chair of geography, 106
  Appointment of L. Mirsky as assistant lecturer in mathematics, 473
  Appointment of Dr. J A Pope as lecturer in mechanical engineering, 473
  Resignation of Dr. E. T. Goodwin as lecturer in mathematics, of Dr. J. H. Read as lecturer in chemistry, of Dr. J. Shirley as lecturer in geology, of Dr. W. Davies as temporary lecturer in geology, of Colonel R. G. Bellamy as lecturer in mechanical engineering, and of Miss M C. Simpson as assistant bacteriologist, 473

  Appointment of P. C Sylvester-Bradley as assistant lecturer in geology, 745
  Appointment of Dr. H McIlwaine as lecturer in biochemistry, 745
  Resignation of Dr. A. Elliott as lecturer in physics, of Dr. J. C. Speakman as lecturer in chemistry, and of F. G. Hannell as lecturer in geography, 745
University College of Wales, Aberystwyth : Appointments in the newly formed Department of Animal Health, 331
University College, Dublin : Appointment of Dr. T. S Wheeler to the chair of chemistry, 230
University College, Hull : Appointment of Paul G. 'Espinasse as lecturer and head of the Department of Zoology, 777
University College, London · Appointment of Prof. C. Daryll Forde to the University of London chair of anthropology, 76
  Appointment of Raymond Irwin to the directorship of the School of Librarianship, 108, 202
  Appointment of J. Z. Young to the University of London chair of anatomy, 415
  Appointment of Prof. Harold Davenport to the Astor chair of mathematics, 443
  Appointment of Prof. F. G. Young to the University of London chair of biochemistry, 471
  Re-opening of the Department of the History and Philosophy of Science, 532
  Title of University of London professor of electrical engineering conferred on Dr. H. E. M. Barlow, 566

SUBJECT INDEX

ABERDEEN · Earthquakes registered during the First Quarter of 1945, 264
Abstracting Service for Human Biology, 714
Accounting · Good Farm (A. C Campbell), *review*, 764
2-Acetyl-amino-fluorene : Glioma in a Rat Fed with (Dr. E. Vazquez Lopez), 296
Acetylphosphatase in Animal Tissues (B. Shapiro and E. Wertheimer), 690
Achievement : British, in the Art of Healing (John Langdon-Davies), *review* by Dr. G. Lapage, 350
Acid Soils : Determination of Factors Injurious to Plants in (Prof. T. Wallace, E. J Hewitt and D. J. D. Nicholas), 778
Acid-fast Bacteria : Inhibitory Action of Dialkyl Succinic Acid Derivatives on the Growth *in vitro* of (Vincent C. Barry and Dr P. A McNally), 48
Acids (Fatty) : Lubrication of Metal Surfaces by (Dr F. P. Bowden, J. N. Gregory and Dr. D. Tabor), 97
Acoustic Control in the Flight of Bats (Prof. H Hartridge), 490, 692 ; (A. J Wilmott), 687 , (Dr D. W. Ewer), 692 ; (Flight-Sergt Martin Wilkinson), 693
Acquired Characteristics : Inheritance and (Prof. Wm. Rowan), 236
Actinomycetes (Meredith's) : Inhibition of the Development of *Fusarium oxysporum cubense* by a Growth Substance produced by (Dr. A. C. Thaysen and K. R. Butlin), 781
Activation Energy of Ionic Migration in Molten Salts (Dr E. Heymann and H. Bloom), 479
Activity of the Respiratory, Vasomotor and Cardio-Regulatory Centres : Influence of Blood Pressure and Blood Flow on the (Prof. C. Heymans), 750
Adenosine Triphosphate . Synthesis of, by an Enzyme System from Ischæmic Muscle (Marian Bielschowsky and Prof. H. N. Green), 117
Administration : Technology and, 671
Administration in Germany : A Plan for Decentralizing, *review* by Prof. W. Fitzgerald, 253
Adsorption of Enzymes on Solid Nucleic Acid (Dr. J. A. V. Butler), 781
Adsorption of Water Vapour by Wheat : Hysteresis in the (Dr J. D. Babbitt), 265
Adsorption Isotherms from Chromatographic Measurements (Dr. E. Glückauf), 748
Adults (Human) : Vitamin A Deficiency and the Requirements of, 11
Advertising : The Economics of (F P. Bishop), *review*, 765
Aerial Bactericides (J E. Lovelock), 782
Aerial Survey in Peace-time . R A F., 2
Aerial Unit for Scientific Work : Memorandum on the Establishment of an (British Ecological Society), 2
Aeronautical Engineering at Bristol, 43
Africa (East) · The Stone Age in (M C Burkitt), 371
  A Contribution to the Study of the Tumbian Culture in (Dr. J. B. S. Leakey and Archdeacon Owen), 371
Africa (East and West) . The Contribution of Colonial Geological Survey to the Development of the Mineral and other Resources of (Sir Edmund Teale), 167
Africa (South) . Archæological Exploration in (Prof. D. M. S Watson), 55
  The Constitution of the Intertidal Fauna and Flora of (Prof. T A. Stephenson), Part 2, 27
  Marine Ecology in, 27
Africa (West) : Report of the Commission on Higher Education in, 345
African Fermented Foods : B Vitamins in (Dr. Leon Golberg, J M. Thorp and Sheila Sussman), 364
African (South) Onychophora (Dr. S. M. Manton), 338
Afterglow Effects in High-Pressure Gases (Dr. J D. Craggs and Dr. J. M. Meek), 21
Age-hardened Alloys : Striated Structure of (Dr M. L. V. Gayler), 333
Ageing : Heat, of GR-S Vulcanisates (Dr J. R. Scott), 10
Ageing Tests (Accelerated) . Use and Misuse of (J. M. Buist and G. N. Welding), 10
Aggregates (Crystalline) · High Permittivity (Prof. Willis Jackson and W. Reddish), 717
Agricultural Attaché at Washington and Agricultural Adviser at Ottawa : Appointment of A. N Duckham as, 138
Agricultural Engineering Record . To recommence publication by the National Institute of Agricultural Engineering, 232
  Publication of No. 1 of the, 500
Agricultural and Forestry Economy of Madras (J A. Wilson), 151
Agriculture : European (United Nations Relief and Rehabilitation Administration), 15
Agrochemistry in the U S.S.R. (Dr E. M. Crowther), 227
Air Navigation : Astronomical (Squadron-Leader Ronald Hadingham), second edition, *review*, 489
Air Photography : Recent Developments in (Wing-Comdr. H. Hamshaw Thomas), 409
Air Photography in the Far East (Dr. V. J Chapman), 604
Air Speed Record by Jet Propelled Aircraft (Group-Captain H. J. Wilson), 597
Aircraft · New Stratosphere, 44
Aircraft Workers Education and Training of, 78
Albumin (Human Serum) : Heterogeneity of (H. Hoch and C. J. O. R. Morris), 234
Alcohol : Synthetic Rubber from (Anselm Talalay and Michael Magat), *review* by Dr. W. J. S. Naunton, 251
Alcohol Vapour · Effect of the Pressure of, on the Operation of the Fast Geiger-Muller Counter (Dr G. D Rochester and C. B. A McCusker), 366
Aldan Region, Eastern Siberia : Post-Jurassic Intrusions of the (Y. A. Bilibin), 178
Algæ and Grasses Californian Marine, 533
Algal Tissues for Microtome Sections : Use of Hydrochloric Acid for Softening (Dr. Kathleen M. Drew), 479
Alkali Halides in Borax and B_2O_3 Glass Systems : X-Ray Study of the Solution of (S. K. Majumdar, B. K. Banerjee and K. Banerjee), 423
Allied Plan for Education (Dr. E. F. Armstrong), 708
Allotropic Modifications of Diamond (Sir C. V. Raman), 22
Alloys (Age-hardened) : Striated Structure of (Dr. M. L. V. Gayler), 333
Allyl Position : Halogenation in the (Dr. William E. Vaughan, Frederick F. Rust and George W Hearne), 53 ; (Dr. W. A Waters), 53
Alpha-Ray Bombardment · Effect of, on Glide in Metal Single Crystals (Prof. E. N da C. Andrade), 113
Aluminium Conductors (Steel-Cored) : Tensile Load on (E. W. W. Double), 305
Aluminium Halides with the Xylenes : Interaction of (H. Campbell and E. F. G. Herington), 389
Alumni Cantabrigienses (Compiled by Dr. J. A. Venn), Part 2, From 1752 to 1900, Vol. 2, Chalmers—Fytche, *review* by Prof F. J. M. Stratton, 248
Alvarenga Prize for 1945 of the College of Physicians of Philadelphia awarded to Dr. Alexander S. Wiener, 79
America (Latin) · Plants and Plant Science in (edited by Frans Verdoorn), *review*, 676
America (South) : The Race Problem in, *review* by Prof A. R. Radcliffe-Brown, 158
American Clingfishes (L P. Schultz), 304
American Work on the Atomic Bomb Project (Prof. N. Feather), 768
Américas · El Indoamericanismo y el Problema Racial en las (Prof. Dr. Alejandro Lipschutz), segunda edicion, *review* by Prof. A. R. Radcliffe-Brown, 158
Amino Acid Composition of Proteins and Foods (Dr. Richard J. Block and Diana Bolling), *review*, 33
Amino-Acids and Peptides : Proteins, as Ions and Dipolar Ions (Edwin J. Cohn and John T. Edsall), *review* by Dr. Kenneth Bailey, 405
p-Aminobenzoic Acid : Production of, by the Tubercle Bacillus (Torsten Ekstrand and Bertil Sjogren), 476
Amino-quinazolines (Prof. A. Killen Macbeth and Harold J. Rodda), 207
Ammonia : Rate of Entrance of, into Muscle Fibres in relation to Carbon Dioxide Tension (Prof. E. J. Conway and P. T. Moore), 270
Amœbiasis in Durban (Major R. Elsdon-Dew), 118
Amyloid-Congo-Red-Complex in Histological Sections : Double-Refringence of the (Dr Peter Ladewig), 81
Anæmia . The Vitamin B Complex in (Dr. Lucy Wills), 87
Anærobic Metabolism of Spermatozoa (Dr T. Mann), 80
Analysis Colorimetric (Noel L Allport), *review* by A. L. Bacharach, 434
  Spectral, of Solid Substances (Dr. J. Eeckhout), 175
Analyst, The : Retirement of Dr. C Ainsworth Mitchell from the editorship, 443
  Appointment of J. H Lane as editor, 443
Analysts · Colour for, *review* by A. L. Bacharach, 434
Analytical Chemistry in Great Britain, with special reference to Microchemistry . The Teaching of (Dr. Cecil L Wilson), 588
Angiosperms . Origin of Haploid-Diploid Twin Embryos in (Dr. P. Maheshwari), 173
  Embryology of, as a Field for Research (Dr. P. Maheshwari), 354
Anglesey : Iron Age Finds from (M. C Burkitt), 309
Anglo-French Conference on Cosmic Rays, 140, 543
Animal in Health, *review* by Dr. John Hammond, 377
Animal Behaviour . Classification and Nomenclature of (Dr. J. S. Kennedy), 754
Animal Breeding and Genetics in Great Britain : Research in, 231
Animal Cells : Demonstration of Mitosis in (Dr. W. S. Bullough), 574
Animal Learning and Evolution (Dr. W. H. Thorpe), 46
Animal Organ Extracts · A Sympathomometic Pressor Substance in (Prof. U. S v Euler), 18
Animal Tissues · Acetylphosphatase in (B. Shapiro and E. Wertheimer), 690
Animals (Domestic and Non-Domestic) : Effect of High Vitamin A in the Diet of (Hilda H. Wheeler), 238
Animals (Farm) : Physiology of (Dr. F H. A Marshall and E. T. Halnan), third edition, *review* by Dr. John Hammond, 377
Anion Permeability Constants : Cation and, for the Muscle Fibre Membrane (Prof. E. J. Conway and P T. Moore), 170
Annual Register for the Year 1944 (edited by Dr. M Epstein), *review*, 489
Anodic Deposit of Protactinium (M. Haïssinsky), 423
Anomalous Inactivation of Heavy Metal Antifouling Paints (Prof. John E. Harris), 206
Antarctic Discoveries : United States (Prof. R. N. Rudmose Brown), 399
Anthropologist · The Posthumous Testimony of an, *review* by Dr. C. S. Myers, 218
Anthropology . Essays in, Presented to Rai Bahadur Sarat Chandra Roy (edited by J. P. Mills, B S. Guha, K. P. Chattopadhayay, D. N. Majumdar and A. Aiyappan), *review* by Prof. J. H. Hutton, 66
  Archæology and, in the U S.S.R (Prof. V. Gordon Childe), 224
Anthropology of Portuguese Timor, *review* by Prof. A. R. Radcliffe-Brown, 129
Anti-bacterial Action of 'Polyporin' against Typhoid, Cholera, Dysentery and *B. coli* (Prof. S. R. Bose), 171
Antibiotic Action : Early Observation of (C. N. Davies), 666
Antibiotic Substance in the Chinese Water-chestnut, *Eleocharis tuberosa* (S. L. Chen, B. L. Cheng, W. K. Cheng and P. S. Tang), 234
Antibiotics : Two New (Dr. G. Lapage), 398
Antibiotics from Moulds (J. Kent and N. G. Heatley), 295
Antibodies : Antigens and, *review* by Capt. J. A. R. Miles, 348
Anti-Chromatic Reflex (Prof. H. Hartridge), 666

Antifouling Paints (Heavy Metal) · Anomalous Inactivation of (Prof. John E. Harris), 206
Antigens and Antibodies, *review* by Capt J. A. R. Miles, 348
Anti-*Hr* Sera (Dr. Philip Levine), 418
Anti-Lewisite (*BAL*) . British (Prof R A Peters, Dr. L. A Stocken and Dr. R. H. S. Thompson), 616
Antimalarial Activity in Tetrahydroacridones and related Substances (Joan M. L. Stephen, Isabel M. Tonkin and James Walker), 629
Antimalarial Drug . A New (Isabel M. Tonkin and T. S. Work), 630
Antimalarial Properties in Quinine Degradation Products · Loss of (P. B. Marshall), 505
Apical Meristem in Ferns : An Experimental Treatment of the (Prof. C W. Wardlaw), 39
Apogonid Fish from New Jersey : Description of a New Genus and Species of (Henry B. Fowler), 395
Apple Drop following Frost : Use of Growth-Promoting Substances in the Prevention of (T. Swarbrick), 691
Apple Trees . Abnormal Lignification in the Wood of some (Dr. A. Beryl Beakbane and Dr. Eleanor C. Thompson), 145 ; *erratum*, 202
  Biennial Bearing of (F. S. Howlett), 304 , (A. B. Burrell), 304 ; (A V. Doren and M. B. Hoffman), 304 ; (M. B Hoffman and J. D Van Geluwe), 304 ; (A E Murneek), 304
Apprenticeship for a Skilled Trade (F. Twyman), 155
Arabian Sea : Earthquake on November 27, 712
Archæological Exploration in South Africa (Prof. D. M. S Watson), 55
Archæology and Anthropology in the U.S.S.R (Prof. V. Gordon Childe), 224
Archaic Fishes · Completion of the Bashford Dean Memorial Volume on (Dr. E. W. Gudger), 533
Archives of the Lakes (Dr. H. Godwin), 383
Argentine-British Medical Centre established in Buenos Aires, 107
Aristotelian Society Proceedings of the, New Series, Vol. 44, Session 1943–1944, *review* by Prof. A. D. Ritchie, 33
Aristotle's Criticism of Plato and the Academy (Harold Cherniss), Vol. I, *review* by Prof A. E. Taylor, 647
Army Education—Educating the Educators, 513
Army School of Education, Eltham Palace (Major T. H Hawkins), 527
Aromatic Nitration ? · Univalent Electron Transfers in (G. A. Benford, C. A. Bunton, E. S. Halberstadt, Dr. E. D. Hughes, Prof. C. K Ingold, G. J Minkoff and R. I. Reed), 688
Arsenic-Resistant Tick (Prof J. Omer-Cooper and A. B. M. Whitnall), 450
Art Galleries as a National Service · Museums and, 249
Arterial Injuries (Medical Research Council, War Memorandum No. 13), 362
Arts and Crafts of the Cook Islands (Mrs. K. Rishbeth), 61
Arylcarbamic Esters and related Compounds · Effect of some, upon Cereals and other Plant Species (Dr. W. G. Templeman and Dr. W A. Sexton), 630
Astronomical Air Navigation (Squadron-Leader Ronald Hadingham), second edition, *review*, 489
Astronomy and Terrestrial Magnetism in the U S S R (Sir Harold Spencer Jones), 324
Astrophysics : Physics and, at the Imperial College (Prof. Herbert Dingle), 562
Atmospheric Oxygen (Earth's) · Stability of the (Alfred Lauck Parson), 504
Atom . Time, Number and the (R. Fortescue Pickard), *review* by F. J. Garrick, 489
Atomic Bomb, 382
  Statements relating to the, 768
Atomic Bomb Project . American Work on the (Prof N Feather), 768
Atomic Co-ordinates Derived from Fourier Systems : Accuracy of (A. D. Booth), 51
Atomic Energy, 609, 768
  Advisory Committee on, 262
  Research in Britain on, 531
  Three-Power Declaration on, 615
Atomic Energy, an International Responsibility, 153
Atomic Energy as a Human Asset (Dr Arthur H. Compton), 687
Atomic Energy and its Implications (joint meeting of the American Philosophical Society and the U.S. National Academy of Sciences on), 687
Atomic Energy for Military Purposes · A General Account of the Development of Methods of Using, under the Auspices of the United States Government, 1940–1945 (Prof. H. D. Smyth), 768
Atomic Energy and Scientific Freedom, 564
Atomic Energy and Its Utilization, 547
Atomic Nuclei (Heavy) · Penetration of Fast Nucleons into (Prof. L. Rosenfeld), 141
Atomization of Carbon : Energy of the Hg—C Bond and the Heat of (Prof. N. V. Sidgwick and H. D Springall), 599
Australia · The Application of Science to Industry in (Sir David Rivett), 472
Automatic Controlling and Recording of Chemical and other Processes : Instruments for the (Institution of Chemical Engineers, the Institute of Physics, and the Chemical Engineering Group of the Society of Chemical Industry joint conference on), 45, 723
Autotrophic Flagellates as the Major Constituents of the Oceanic Phytoplankton (Dr. W. R. G. Atkins), 446
Autoxidation of Linoleic Acid (Sune Bergstrom), 717
Avoidance of Obstacles by Bats (Prof. H. Hartridge), 55

BACILLUS (Tubercle) · Production of *p*-Aminobenzoic Acid by the (Torsten Ekstrand and Bertil Sjogren), 476
Bacteria in relation to the Milk Supply (G. H. Chalmers), third edition, *review*, 406
Bacteria (Acid-fast) . Inhibitory Action of Dialkyl Succinic Acid Derivatives on the Growth *in vitro* of (Vincent C. Barry and Dr. P. A. McNally), 48
Bacteria (Legume Nodule) . Effective and Ineffective Strains of (Dr. H. G. Thornton), 654
Bacterial Virus Mutations in (S. E. Luria), 304
Bactericides : Aerial (J E. Lovelock), 782
Bacteriological Purposes Preparation of Silicic Acid Jellies for (Bjorn Ingelman and Ingvar Jullander), 572
Bacterium brunneum · Cultures of (William J. Ellis), 365
Bacterium coli : Effect of Sulphanilamide on the Sugar Consumption of (N. Klissiunis), 178
Bacterium coli (Typhoid, Cholera, Dysentery and) . Anti-bacterial Action of 'Polyporin' against (Prof S. R. Bose), 171
Ball Lightning, 293
Baly Medal of the Royal College of Physicians awarded to Prof S. A. S Krogh, 531
Barium Titanate : Crystal Structure of (W F. Forrester and R. M. Hinde), 177
Barley Grain · Some Factors concerned in the Process of Starch Storage in the (H K Archbold), 70
Barley Seedlings on Very Acid Soil Accumulation of Sugars in (T W. Barnes), 692
Bat : Unusual State at Birth of a (T. S. Jones), 365
Bates Method for Good Sight without Glasses (Dr. William H. Bates), *review*, 281
Bats : Acoustic Control in the Flight of (Prof H. Hartridge), 490, 692 ; (A. J. Wilmott), 687 ; (Dr. D. W. Ewer), 692 , (Flight-Sergt. Martin Wilkinson), 693
  Avoidance of Obstacles by (Prof. H Hartridge), 55
Bearded Iris Seeds . Germination of (L F. Randolph and L. G. Cox), 395
Beckmann Rearrangement . Mechanism of the (Flight-Lieut. Bryan Higman), 242 ; (M J S. Dewar), 688
Beetles (Powderpost) · Protection of Timber against, 16
Behaviour of the Common Centipede *Lithobius forficatus* (Capt. J. L. Cloudsley-Thompson), 537
Beit Memorial Fellowships for Medical Research : Annual Report of the Trustees for the Year 1944–45, 140
  Elections, 140
Belgian Biological Publications during the War, 166
Belgique : Léon Fredericq et les débuts de la physiologie en (Prof. Marcel Florkin), *review* by Prof. C. Lovatt Evans, 764
Belgique pendant l'occupation Allemande 1940–1944 : Les états de carence en (Lucien Brull, G. Barac, T. Brakier-Zelkowicz, P. Clemens, R. Crismer, J. Deltombe, A. Divry, L. Dubois, L. Dumont, L. Dumont-Ruyters, A. Lambrechts, R. Neuprez, A Nizet, M -J. Op de Beeck, J Piersotte et A. Thomas), *review* by Major J Marshall, 551
Belgium : Deficiency Diseases in, *review* by Major J. Marshall, 551
Bengal · Artificial Production of Ergot in the Tropical Plains of (J. C. Saha and S. K. Bhattacharjee), 363
Benzene . Near Ultra-Violet Emission Bands of (Prof. R. K. Asundi and M. R. Padhye), 368 ; (Prof. C K. Ingold), 569
Benzidine and related Rearrangements . Mechanism of the (M. J. S. Dewar), 784
3 : 4-Benzpyrene from Coal Tar (Dr. I Berenblum), 601
Beryllium . Atomic Weight of (Johannsen), 179
Bessel Functions . A Treatise on the Theory of (Prof. G. N. Watson), second edition, *review* by Prof L. M. Milne-Thomson, 190
Bibliography on British Industry and Commerce (Sheffield City Libraries), 44
Biochemical Research Foundation of the Franklin Institute . Reports of the, 331
Biochemistry . Advances in Enzymology and related Subjects of (edited by F. F Nord and C. H. Werkman), Vols 4 and 5, *review* by Dr. J. H. Quastel, 611
Biochemistry of Mental Disorder (Psychiatry section of the Royal Society of Medicine meeting on), 101
Biological Abstracts . Establishment of Section H for Abstracts of Human Biology, 714
Biological Control of Insect and Plant Pests (Dr. W R. Thompson), 271
Biological Fibres and the Problem of Muscle : Structure of (Dr. W. T Astbury), 89
Biological Publications · Belgian, during the War, 166
Biological Work in Finland : Recent (Dr. G. H. Beale), 357
Biology . Reactions at Interfaces and their Significance in (Dr. J. F. Danielli), 468
  Evolutionary, and related Subjects in the U.S.S.R. (Dr. Julian Huxley), 254 ; *errata*, 293
  (Human) . Abstracting Service for, 714
  Middle East Field, 532
  Self-sufficient, *review* by Dr. C. H. Waddington, 731
Biology, Chemistry and Physics in India : Research Fellowships in, 107
Biology and Medicine · Direct Chemical Action upon Nerve Centres in (Prof. Lena Stern), 7
Bionomics of *Hylemyia cinerella* Fallen (Dr. M. Hafez), 48
Birds : Detection of, by Radar (David Lack and G. C. Varley), 446 ; (Lieut. H. A C. McKay), 629
  The Edibility of (Dr. Hugh B. Cott), 736
  (Bower) : Display and Bower Building in (E. Nubling), 168
  Garden (Phyllis Barclay-Smith), *review*, 34
Birds of California : The Distribution of the (Joseph Grinnell and Alden H. Miller), *review*, 34
Birth of a Bat · Unusual State at (T S. Jones), 365
Black Widow, America's Most Poisonous Spider (Raymond W. Thorp and Weldon D. Woodson), *review* by T. H. Savory, 253
Blackbird . The (A F. C. Hillstead), *review* by Sir D'Arcy Thompson, 318
Black-Body Intensity : Departure of Long-Wave Solar Radiation from (Sir Edward Appleton), 534
Blackwell Prize awarded to Dr. Archibald Clow, 45
Blind: Sensory Devices for the (Committee set up by the Council of St. Dunstan's), 200
Blind Seed Disease of Rye-grass (Malcolm Wilson, Mary Noble and Elizabeth G Gray), 178
Blood in Children . Atlas of the (Dr. Kenneth D. Blackfan and Dr. Louis K. Diamond), *review* by Prof. Thos. B. Davie, 192
Blood (Normal) . Crystalline Hæmolytic Substance from (Dr. H. Laser and Dr. E. Friedmann), 507
Blood Pressure and Blood Flow . Influence of, on the Activity of the Respiratory, Vasomotor and Cardio-Regulatory Centres (Prof. C. Heymans), 750
Blood Transfusion : *Rh* and, 625
Blood-sucking Parasites : Hæmoglobin in (Prof H. Munro Fox), 475
Boll Rot of the Cotton Plant (Internal), caused by Insect Punctures (*Dysdercus* sp.), through Selection of Resistant Strains : Control of (Prof. Teodoro Boza Barducci, Prof. Germán García Ráda and Prof. Johannes Wille), 235
Bone : Recent Investigations on the Growth of (Prof. P. Lacroix), 576

ooks : Recent Scientific and Technical, Supp. ii, July 28 ; Supp. ii, August 25 , Supp. ii, September 29 ; Supp. ii, October 27 ; Supp. ii, November 24 ; Supp. ii, December 29
Books and Journals for Holland and Denmark, 263
Borax and 'B_2O_3 Glass Systems : X-Ray Study of the Solution of Alkali Halides in (S. K Majumdar, B K. Banerjee and K. Banerjee), 423
B_2O_3 Glass Systems (Borax and) : X-Ray Study of the Solution of Alkali Halides in (S. K. Majumdar, B. K Banerjee and K. Banerjee), 423
Boron Phosphate in Fireside Deposit from an Economizer · Occurrence of (L. M. Clark and J. Haslam), 302
Botanist for India at Kew, 444
Botany in Latin America, *review*, 676
Bower Birds : Display and Bower Building in (E Nubling), 168
Boys (Charles Vernon) Prize of the Physical Society awarded to Dr. A. H. S. Holbourn, 685
Bread in Jersey during German Occupation (Dr. D W. Kent-Jones and Dr. A. J. Amos), 336
'Bridge' for Two-Solution Cells : A Convenient (Dr. S. M Neale), 506
Bristol : Aeronautical Engineering at, 43
Britain : Chinese Visitors to, 201
  Use of Fertilizers in, 776
  Food Policy in, 292
  National Maps of (Ministry of Town and Country Planning), 776
  Reform of the Patent Law in (Prof. Michael Polanyi), 54 ; (The Writer of the Article), 54
  Research in, on Atomic Energy, 531
  Government Support for Research Associations in (Herbert Morrison), 597
  A State Scientific Service in, 643
  Higher Technological Education in, 699
  Timber Resources of, *review* by Major T. H. Hawkins, 613

  Surface, in the U.S S.R. (Prof. N. K. Adam), 284
Chemistry in China, 511
Chemistry of Natural Colouring Matters (Dr. Fritz Mayer), translated and revised by Dr. A. H. Cook, *review* by Prof. W. Baker, 552

Chemistry of Penicillin (Committee on Medical Research, Washington, and the Medical Research Council, London), 766
Chemistry and Technology of Food and Food Products (edited by Dr. Morris B Jacobs), Vol 2, *review* by Dr T Moran, 220
Chemistry, Physics and Biology in India : Research Fellowships in, 107
Chemists : Social Security for (British Association for Chemists, London Section, open meeting on), 331
Chemotherapy of Tuberculosis (Dr. M. A. Soltys), 210
Child : A Fatal Case of D.D T. Poisoning in a (Major K. R Hill and G. Robinson), 780
Child Guidance . An Introduction to (W Mary Burbury, Edna M. Balint and Bridget J. Yapp), *review* by Dr. Alan Maberly, 157
Child's Blood in Health and Disease, *review* by Prof Thos. B. Davie, 192
Children : Atlas of the Blood in (Dr. Kenneth D. Blackfan and Dr. Louis K. Diamond), *review* by Prof. Thos. B. Davie, 192
  (Young) . Intelligence Tests for (Prof. C. W. Valentine), *review* by Dr. John Cohen, 349
China : Chemistry in, 511
Chinese Visitors to Britain, 201
Chinese Water-chestnut, *Eleocharis tuberosa* : An Antibiotic Substance in the (S L. Chen, B. L Cheng, W. K Cheng and P S. Tang), 234
Cholera, Dysentery and *B coli* (Typhoid,) : Anti-bacterial Action of 'Polyporin' against (Prof S. R. Bose), 171
Choline Esterases (Dr. K-B Augustinsson), 303
Chondrosamine : A Constitutional Synthesis of (Dr. Sybil P James, Dr F. Smith, Dr M. Stacey and Dr. L. F. Wiggins), 308
Chree (Charles) Medal and Prize of the Physical Society awarded to Dr. John A. Fleming, 658
Chromatographic Measurements : Adsorption Isotherms from (Dr E. Gluckauf), 748
Chromatography of Two Solutes (Dr. E. Gluckauf), 205, 571 ; (A C Offord and Dr. J Weiss), 570
Chromatophore Reactions . Pigments and, of *Polycelis nigra* and *Planaria lugubris* (Capt. J L. Cloudsley-Thompson), 294
Chromium, Cobalt and Nickel in Eruptive Rocks (Vanadium,) : Distribution of (Prof. L. R. Wager and R L. Mitchell), 207
Chromium Oxide as a Promoter in Catalysts for the Fischer-Tropsch Synthesis (Sir J C. Ghosh and S L. Sastry), 506
Chromosomes : Human (Prof. M. E Varela), 755
  Phosphatase on (Dr. J F. Danielli and D. G Catcheside), 294
Civil Service : The Scientific, 643
Classification of Recent Philosophy, *review* by Prof A. D. Ritchie, 376
Classification and Nomenclature of Animal Behaviour (Dr J. S. Kennedy), 754
Clever : The Good and the (Master of Balliol), 744
Climates (Dry) : Chalk-washing of Sugar-Beet in (Kolossov), 304
Climatology (Prof. Bernhard Haurwitz and Prof. James M. Austin), *review* by Prof D Brunt, 157
  Methods in (Victor Conrad), *review*, 317
Clines : Progressive (F. W. Braestrup), 337
Clingfishes . American (L. P. Schultz), 304
Clinical Technique : Interpretation of Fantasy as a, *review* by Dr. John Cohen, 701
Clock-Regraduations and Relativistic Cosmology (Dr. T J. Willmore), 748
Closure and Partial Separation of a Metallic Contact (Dr. Alan Fairweather), 545
Clover Nodule Formation associated with the Volume of the Medium Occupied by the Roots A Factor in (Dr. P. S. Nutman), 20
Coagulation : Heat, of Muscle Proteins (Dr. E. C. Bate-Smith and J. R. Bendall), 632
Coal Gas Flames : Influence of Sulphur Oxides on the Luminosity of (Dr. G. Whittingham), 207
Coal Tar : 3 : 4-Benzpyrene from (Dr I. Berenblum), 601
Coals Infra-Red Spectra of (C. G. Cannon and Dr. G. B. B. M. Sutherland), 240
Co$_2$-Al$_5$. Unit Cell and Space-Group of (Audrey M. B. Parker), 783
Cobalt and Nickel in Eruptive Rocks (Vanadium, Chromium,) : Distribution of (Prof. L. R Wager and R L. Mitchell), 207
Coco-nut : Nutritive Value of (Dr. J. M Vanderbelt), 174
Cod (*Gadus callarius* L.) in the Newfoundland Area including Labrador : A Biological and Economic Study of the (Dr Harold Thompson), 213
Coefficients (Termination) . Propagation and, for Vinyl Acetate Photo-polymerization (G. M Burnett and Prof H. W. Melville), 661
Cohesion : Degree of Association of Water from the Energy of Viscosity and the Work of (L. Grunberg and Dr. A. G. Nissan), 335
Col du Lautaret, Hautes-Alpes . Cosmic Radiation observed at the (Jean Daudin), 420
Collaboration . International, 78
Colloidal Solutions : Viscosity of Liquids and (Academy of Sciences of the U S S.R conference on), 147
Colombia (off) : Earthquake on March 17, 264
Colonial Geological Survey : The Contribution of, to the Development of the Mineral and other Resources of East and West Africa (Sir Edmund Teale), 167
Colonial Research 1944–45, 509
Colonial Universities and their Functions, 345, 373
Colonies : Report of the Commission on Higher Education in the, 345
  Report of the West Indies Committee of the Commission on Higher Education in the, 345
  (British) : Research and Development in the, 509
  (British) : Scientific Research in India and the, 758
Colorado Beetle in England during the War, 776
Colorimetric Analysis (Noel L Allport), *review* by A. L. Bacharach, 434
Colour Reaction in Yeast (Mignon Malm), 52
Colour Sensitivity of the Fovea Centralis (E. N. Willmer and W. D. Wright), 119,
Colour Vision Darkened Violet in (Dr. R. W. Pickford), 506
  Electrotonus in (Prof S V. Kravkov and L P. Galotchkina), *erratum*, 626
Colouring Matters (Natural) : The Chemistry of (Dr. Fritz Mayer), translated and revised by Dr. A H. Cook, *review* by Prof. W. Baker, 552
Comets ? . What are (Enrique Gaviola), 79
Commonwealth (British) : Research within the (Society for Visiting Scientists meetings to discuss the organisation of), 660
Community : Museums and the, 165
  Universities and the Needs of the, 183
Compasses : Repeating (W. E. May), 593
Complex Variable : Functions of a, *review* by J. H. Pearce, 67
Compregnated Wood (D. Narayanamurti and Kartar Singh), 787
Compromise and Integration (Colonel L. Urwick), 93
Concept of Mental Maturity (Prof. A. W. Wolters), 494
Conditioned Excitors and Human Sense Organs (Prof Krikor Kekcheyev), 573
Conditioned Reflexes : Research in the U.S S.R. on, 455
Conditioning of Plywood, 139
Conductors (Steel-Cored Aluminium) : Tensile Load on (E W. W Double), 305
Congo Red Fibrin Powder for Experiments on Proteolytic Enzymes (D G. Duncan and Dr. H. Zwarenstein), 112
Coniques : Les (Prof. Henri Lebesgue), *review* by Prof. H. T. H. Piaggio, 648
Contact (Metallic) : Closure and Partial Separation of a (Dr. Alan Fairweather), 545
Continuity and Discontinuity (Prof. J. K. Robertson), 271
Control of Germany and Japan (Dr. Harold G. Moulton and Dr. Louis Marlio), 64
Control and Recording : Automatic, in Chemical and other Processes (Institution of Chemical Engineers, the Institute of Physics, and the Chemical Engineering Group of the Society of Chemical Industry conference on), 45, 723
Controlled Projection (1944) (arranged by John C. Raven), *review* by Dr. John Cohen, 701
Cook Islands . Arts and Crafts of the (Mrs. K. Rishbeth), 61
Co-operation International, in Social and Economic Fields, 231
Co-ordinates (Atomic) : Accuracy of, Derived from Fourier Systems (A D Booth), 51
Copley Medal of the Royal Society awarded to Dr. O T. Avery, 596, 694
Corona (Solar) : A Physical Theory of the (Dr. A. Hunter), 649
Corpuscles of the Hen (Red) : Life-Cycle of the (Prof G. Hevesy and J. Ottesen), 534
Correlation (Multiple) : Estimation of, by means of Stereographic Projection (G F. K. Naylor), 58
Corrosion of Metallic Couples : Hydrogen Overvoltage as a Factor in the (L F LeBrocq and H. C. Cocks), 536
Corrosion of Metals (Institute of Physics, London and Home Counties' Branch, discussion on), 435
Cosmic Radiation (Dr L. Jánossy), 704
Cosmic Radiation observed at the Col du Lautaret, Hautes-Alpes (Jean Daudin), 420
Cosmic Rays : Anglo-French Conference on, 140, 543
Cosmic Rays and Kinematical Relativity (Prof. J B. S. Haldane), 266 ; (Prof. Herbert Dingle), 389
'Cosmic Static' (Grote Reber), 396
Cosmogony of the Solar System : A New (Dr. A. Hunter), 378
Cosmology (Relativistic) : A New Approach to (Prof. L Infeld), 114
  Clock-Regraduations and (Dr. T J Willmore), 748
Cottid Fishes : Marine, of California (Rolf L. Bolin), 395
Cotton Plant : Control of Internal Boll Rot of the, caused by Insect Punctures (*Dysdercus* sp.), through Selection of Resistant Strains (Prof. Teodoro Boza Barducci, Prof. Germán García Ráda and Prof. Johannes Wille), 235
Cracking (Exposure) : The Mechanism of (Dr R G Newton), 10
Cracking (Rubber) : The Mechanism of (E F. Powell and V. E. Gough), 11
Crafts of the Cook Islands : Arts and (Mrs. K. Rishbeth), 61
Crater Fumaroles of Kibo and Seismic Activity during 1942–45 (J J. Richard), 352
Croonian Lecture of the Royal Society (Dr. W. T Astbury), 89 , (Prof. August Krogh), 542
Crystalline Aggregates : High Permittivity (Prof Willis Jackson and W. Reddish), 717
Crystalline Hæmolytic Substance from Normal Blood (Dr H. Laser and Dr. E. Friedmann), 507
Crystallization and Identity of the Triose and Triosephosphate Dehydrogenases of Muscle (Ranwel Caputto and Dr. Malcolm Dixon), 630
Crystallography in the U.S S R. (Dr. W. A Wooster), 256
Crystals : Some Problems of the Theory of (Prof Max Born), 705
  (Single Metal) . Effect of Alpha-Ray Bombardment on Glide in (Prof. E N. da C. Andrade), 113
Crystal Plates (Non-Piezo-Electric) : Shear Modes in (Prof. S. Bhagavantam and J Bhimasenachar), 23
Crystal Structure of Barium Titanate (W. F. Forrester and R, M. Hinde), 177
Crystal Structure of Diamond (G. N Ramachandran), 83
Culex (*Barraudius*) *modestus* Ficalbi (Diptera, Culicidæ) obtained in the South of England : Records of (John F Marshall), 172
Cultural Organisation of the United Nations (Educational and) : Draft proposals for an, 263 ; (Prof. Norman Bentwich), 445
Cultural Organisation (Educational and) : A United Nations—Introduction (Dr. E F Armstrong), 553 ; Science and the United Nations (Dr. Julian Huxley), 553 ; World Co-operation in Science (J. G. Crowther), 556 ; A Permanent International Scientific Commission (Prof. J D Bernal), 557 ; The Place of Science and International Scientific Co-operation in Post-War World Organisation, 558
  Scientific Delegates to the, 565
Culture : A Scientific Theory of, and other Essays (Bronislaw Malinowski), *review* by Dr. C S Myers, 218
Cytological Reactions Induced by Inorganic Salt Solutions (Albert Levan), 751
Czech Botanists during the War, 416
Czechoslovakia Scientific Co-operation with, 416

DANISH Research Expedition, 565
Danube Basin and the German Economic Sphere (Dr. Antonin Basch), *review* by Capt. Maurice Bruce, 551
Darkened Violet in Colour Vision (Dr. R W Pickford), 506
Darwin (Charles) memorial rooms at Down House . Re-opening of the, 533
Data for Identification Purposes : Indexes of (Dr. A F Wells), 535
Davy Medal of the Royal Society awarded to Prof. Roger Adams, 596, 695

aylight Rays (Ultra-Violet and) : Behaviour of, in the Solar Cycle (Dr. J R. Ashworth), 115
D.T. · Control by, of Flies Breeding in Percolating Sewage Filters (T. G. Tomlinson), 478
  Insecticidal Action of (J R. Busvine), 169
  Phytopathological Uses of the new Insecticide, (H. Martin and R. L. Wain), 168
  Toxicity of, to the Housefly (E. A Parkin and A A Green), 745
.D T. in Soap : Efficacy of (G A. Campbell, F. C Hymas and Dr. T. F. West), 749
D T Poisoning in a Child : A Fatal Case of (Major K. R. Hill and G. Robinson), 780
ean (Bashford) Memorial Volume on Archaic Fishes : Completion of the (Dr. E. W Gudger), 533
ecca Navigator System, 542
efence (National) : Science and, 29, 63, 457
eficiency Diseases in Belgium, *review* by Major J. Marshall, 551
egeneration and Repair of Nerve Fibres : Structure, (J. Z. Young), 132
egradation Products : Primary, of Mepacrine in Human Urines (D Ll. Hammick and S. F. Mason), 718
ehydrogenases of Muscle (Triose and Triosephosphate) : Crystallization and Identity of the (Ranwel Caputto and Dr. Malcolm Dixon), 630
Demobilization, Rehabilitation and Land Use, 429
Denmark (Holland and) : Books and Journals for, 263
Density in Solutions (Interfacial Tension and) : Time Dependence of (Prof. George Antonoff), 301
Dental Teaching and Research in Great Britain Nuffield Foundation to make grants for, 417
Dermatoses : Relation of the Gonadal Hormones to certain (Dr Georges Garnier), translated by Major James Marshall, 339
Desert Locust · Presence of Reddish Pigment in Eggs and Ovarioles of the, and its Probable Phase Significance (Dr. M. L. Roonwal), 19
Desiccation : Losses of Nitrous Nitrogen from Soils on (Dr M. R. Madhok and Fazal-Uddin), 49
Detection of Birds by Radar (David Lack and G. C. Varley), 446 ; (Lieut. H A. C McKay), 629
Development (Research and) : in the British Colonies, 509
  in the United States, 360
Dialkyl Succinic Acid Derivatives : Inhibitory Action of, on the Growth *in vitro* of Acid-fast Bacteria (Vincent C Barry and Dr. P. A. McNally), 48
Diameters of the Living Eye by means of X-Rays : Measurement of the (Prof. Arnold Sorsby and A. D. O'Connor), 779
Diamine Oxidase · Action of Mepacrine on (Dr. H. Blaschko and Ruth Duthie), 113
Diamond : Allotropic Modifications of (Sir C. V Raman), 22
  Crystal Structure of (G. N. Ramachandran), 83
  Infra-Red Spectrum of (K. G Ramanathan), 23
Diatomic Oxides : Spectra of, by the Method of Exploded Wire (B. Rosen), 570
Dibenzyl : Structure of (Dr. G. A. Jeffrey), 82
Dibenzylphosphoryl Chloride for Phosphorylations : Use of (Dr. A. Deutsch and O. Ferno), 604
Dickinson Presentation Fund, 417
Dielectric Constants of some Titanates (Dr. B. Wul), 480
Dielectric Surface (Lichtenberg Figures) : Electric Discharge on a (A. Morris Thomas), 451
Dienoestrol and Stilboestrol Solutions : Instability of (A. E. Wilder Smith and P. C. Williams), 718
Diet : Hospital (Dr. G. Lapage), 725
Diet of Domestic and Non-Domestic Animals : Effect of High Vitamin A in the (Hilda H. Wheeler), 238
Dietitians : The Training, Qualifications and Function of (Nutrition Society conference on), 566
Difference Tones (A. J. King), 536
  Production of (Prof. Frank Allen), 84
Differentiation of Nuclear Substances (Ch. Wunderly), 750
Diffusion Pump : Comparative Vacua Produced by Different Oils in a (Kamalesh Ray and Nanda Dulal Sengupta), 636
Diffusion Pumps : Performance of (Dr. K. C. D. Hickman), 635
Dilthey, Wilhelm—an Introduction (Prof. H. A. Hodges), *review* by Dr. A. D. Lindsay, 461
9 : 10-Dimethyl-1 : 2-Benzanthracene : Spontaneous Regression of Histologically Malignant Tumours Induced in Rabbits by (Stephan Beck), 238
2 : 6-Dimethyl-β-d-Galactopyranose (Crystalline) : The Isolation of, from the Methylated Polysaccharide—A Polysaccharide from *Gigartina stellata* (Eric T. Dewar and Dr. E. G. V. Percival), 633
Diphyllobothriidæ in Ireland : Occurrence of the (J. R. Harris and Dr. M. D. Hickey), 447
Dipropyl Ketone at Low Temperatures : Fluorescence of (Dr. S. C. Sirkar and B. M. Bishui), 333
Directiveness of Organic Activities (Dr. E. S. Russell), *review* by Dr. C. H. Waddington, 731
Discontinuity : Continuity and (Prof. J. K. Robertson), 271
Disease : Contributions of the Imperial College to the Conquest of (Lord Rayleigh), 520
Disease (Human) : Tyroglyphid Mites and (Dr. G. Lapage), 427
Disease (Health and) : The Child's Blood in, *review* by Prof. Thos. B. Davie, 192
Diseases : Cereal (W. C. Moore), 533
  Deficiency, in Belgium, *review* by Major J. Marshall, 551
  The Venereal, 501
Documentary Reproduction : Microfilm and other Means of (Association of Special Libraries and Information Bureaux conference on), 24
Double-Refringence of the Amyloid-Congo-Red-Complex in Histological Sections (Dr. Peter Ladewig), 81
Draper (Henry) Medal of the United States National Academy of Sciences for 1945 awarded to Paul W. Merrill, 575
Drawings (Line) : Lantern Slides of (Dr. G. D. Yarnold and L. Heath), 574
Dry Rot of Seed Potatoes : Control of, by Dusting (Dr. C. E. Foister, Dr. A. R. Wilson and Dr. A. E. W. Boyd), 394
Dublin Colloquium, 1945 (Prof. Max Born), 704
Duddell Medal for 1945 of the Physical Society awarded to Prof. J. T. Randall, 685
Durban . Amoebiasis in (Major R Elsdon-Dew), 118
Dusting : Control of Dry Rot of Seed Potatoes by (Dr. C. E Foister, Dr. A. R Wilson and Dr. A. E. W. Boyd), 394
Dwarf Binaries · White (Dr. W. J. Luyten), 293
Dysentery and *B. coli* (Typhoid, Cholera,) . Anti-bacterial Action of 'Polyporin' against (Prof. S. R. Bose), 171

EARTH : Thermal History of the (Dr. E. C. Bullard), 35
Earth and Planets · A Meteoric Theory of the Origin of the (Dr. O. J. Schmidt), 185
Earth Wire : Surge Characteristics of a Three-Phase Transmission Line with (W. G. Hawley), 305
Earth's Atmospheric Oxygen · Stability of the (Alfred Lauck Parson), 504
Earth's Magnetism (Prof. Sydney Chapman), 45
Earthquake
  in the Arabian Sea on November 27, 712
  off northern California on May 19, 545
  In Chiriqui Province, Panama, on June 3, 545
  off Colombia on March 17, 264
  off the coast of Japan on January 12, 79 ; on February 10, 79
  east of Kamchatka on April 15, 201
  off Mazatlan, Mexico, on April 15, 201
  west of Mexico on May 19, 201
  east of New Zealand on April 19, 201
Earthquakes
  During the First Quarter of 1945, 264
  registered in the Isle of Wight by E. W. Pollard during March, 79 ; during April and May, 201 , during June, 545 ; on November 27, 712
  registered at King's College Observatory, Aberdeen, during the First Quarter of 1945, 264 ; during April, May and June, 545
  registered in New Zealand, during January, 79 ; during February and March, 264 ; during April, 544 , during 1942 and 1943 (R. C. Hayes), 396
  registered in Spain, during January, 79 , during February, 79 ; during March, 264 ; during April, 544
  Recent, 79, 201, 544
  Study of, *review* by E. Tillotson, 95
Earthquakes in California . Frequency of (B. Gutenberg and C. F. Richter), 371
Earthworm : Motor Response from Giant Fibres in the (Dr. W. A. H. Rushton), 109
Ecological Studies (Tropical): Need for Development of (Dr. C. J. Chapman, C. O. Flemmich, A. L. Griffith, J. L. Harley, R. Hobbins, C. H. Holmes, C. de Rosayro and J. Wyatt-Smith), 627
Ecology : Marine, in South Africa, 27
Ecology in the Service of Man, *review* by Sir John Russell, 675
Economic Fields (Social and) : International Co-operation in, 231
Economic and Social Council : The Scientist and the (Guy B. Gresford), 625
Economics of Advertising (F. P. Bishop), *review*, 765
Economizer . Occurrence of Boron Phosphate in Fireside Deposit from an (L. M. Clark and J. Haslam), 302
Economy in Sampling (G. A. Barnard), 208
Edibility of Birds (Dr Hugh B. Cott), 736
Education : The Allied Plan for (Dr. E. F. Armstrong), 708
  Principles of, *review* by T. Raymont, 676
  Science and (Association of Scientific Workers, Leeds Branch, conference on), 56
  Science and, in India, 291
  The Science Film in (Miss Dorothy Grayson), 426
  Sex—Aims, Possibilities and Plans (Cyril Bibby), 412, 438
  (Adult) . Science in (C. V. Bellamy), 57
  Army—Educating the Educators, 513
  The Army School of, Eltham Palace (Major T. H. Hawkins), 527
  Higher, in the Colonies (Report of the Commission on), 345
  Higher, in the Colonies (Report of the West Indies Committee of the Commission on), 345
  Higher, in West Africa (Report of the Commission on), 345
  Higher Technological, in Britain, 699
  (Technical) : Part-time (Dr. P. D. Ritchie), 57
  University, and Business, 671
Education, its Data and First Principles (Sir Percy Nunn), third edition, *review* by T. Raymont, 676
Education in H.M. Forces, 107
Education in International Morality : Problems of (United Nations Fellowship discussion on), 444
Education of the Technologist (Prof. J. B. Speakman), 57
Education and Training of Aircraft Workers, 78
Educational Reconstruction in the United Nations : Post-War (edited by Prof. I. L. Kandel), *review*, 318
Educational and Cultural Organisation of the United Nations (Prof. Norman Bentwich), 445
Educational and Cultural Organisation : A United Nations—Introduction (Dr. E. F. Armstrong), 553 ; Science and the United Nations (Dr. Julian Huxley), 553 ; World Co-operation in Science (J. G. Crowther), 556 ; A Permanent International Scientific Commission (Prof. J. D Bernal), 557 ; The Place of Science and International Scientific Co-operation in Post-War World Organisation, 558
  Scientific Delegates to the, 565
Egg of *Ixodes ricinus* L : Hatching of the (D. R. Arthur), 538
Egg-Yolk Medium : Respiration of Spermatozoa in (J. Tošić and Dr. Arthur Walton), 507
Eggs and Ovarioles of the Desert Locust : Presence of Reddish Pigments in, and its Probable Phase Significance (Dr. M. L. Roonwal), 19
Electric Discharge on a Dielectric Surface (Lichtenberg Figures) (A. Morris Thomas), 451
Electric Transmission : Surge Characteristics in, 305
Electrical Engineers : British, and the War (Dr. P. Dunsheath), 482
Electrical Hypothesis of Synaptic and Neuromuscular Transmission (Prof. J. C. Eccles), 680
Electrical Moisture Meter (Dr. L. Hartshorn and W. Wilson), 16
Electrical Resistance of Liquid Metals (Prof. K. S. Krishnan and A. B. Bhatia), 503

Electrical Transients   The Simple Calculation of (G. W. Carter), *review* by Dr. L. E. C. Hughes, 6
Electricity—Public or Private Monopoly ? (F. Hamlyn Dennis), *review* by C. W. Marshall, 585
Electricity Supply in Matabeleland : Future of (A R. Sibson), 168
Electricity Supply Organisation, *review* by C. W. Marshall, 585
Electricity Supply Systems : Operational Control of (W. Kidd and E M. S McWhirter), 361
Electrocardiography : New Basic Concepts In—The Ventricular Gradient (Dr. W. F. Berg), 590
Electromagnetism and Gravitation : A Classical Theory of (Dr. H. C Corben), 388
Electromechanical Analogies (Dr. A. Bloch), 151
'Electron Radiography' using Secondary β-Radiation from Lead Intensifying Screens (H. S. Tasker and S. W Towers), 50
Electron Shadow-Micrographs of Hæmocyanin Molecules (Prof. Robley C. Williams and Dr. Ralph W. G. Wyckoff), 68
Electron Transfers : Univalent, in Aromatic Nitration ? (G. A Benford, C. A. Bunton, E. S. Halberstadt, Dr. E. D Hughes, Prof. C K Ingold, G J. Minkoff and R. I. Reed), 688
Electronic Phase Velocity . A New Occurrence of the (W E. Benham), 204
Electrotonus in Colour Vision (Prof S V. Kravkov and L. P. Galotchkina), *erratum*, 626
Elements Rage : The (Frank W. Lane), *review* by Prof. D. Brunt, 703
Eleocharis tuberosa : An Antibiotic Substance in the Chinese Water-chestnut, (S. L. Chen, B. L. Cheng, W. K. Cheng and P S. Tang), 234
Elliot (Daniel Giraud) Medal of the United States National Academy of Sciences, for 1941 awarded to Th. Dobzhansky, 575 ; for 1942 awarded to Sir D'Arcy Thompson, 575 ; for 1943 awarded to Karl Spencer Lashley, 575
Elliptische Funktionen . Vorlesungen uber allgemeine Funktionentheorie und (Prof Adolf Hurwitz), dritte auflage, *review* by J. H. Pearce, 67
Embedding Medium : Ester Wax, a New (Dr. H. F Steedman), 121
Embryo . The Early Human, *review* by Dr. C H. Waddington, 375
Embryology . Human (Prof. W. J. Hamilton, Prof. J. D. Boyd and Prof. H. W. Mossman), *review* by Dr D. V. Davies, 315
Embryology of Angiosperms as a Field for Research (Dr. P. Maheshwari), 354
Emission Bands of the Fluctuation Type in the Spectrum of Iodine (Prof R K. Asundi and P. Venkateswarlu), 452
Enamel Cuticle (Nasmyth's Membrane) and Tartar Deposition in the Ferret (Dr. J. D. King), 572
End-Group Determination to Structural Problems in the Polysaccharides : Application of New Methods of (F. Brown, Sonia Dunstan, T. G. Halsall, Prof E. L. Hirst and J. K. N. Jones), 785
Endocrinology . Recent Advances in (Prof. A. T. Cameron), fifth edition, *review*, 34
Endodermal Pellogen in the Stem of *Paederia foetida* Linn. (Dr. P Maheshwari), 116
Energies (Low) : Energy Spectrum of Mesotrons at (S. K. Ghosh and N. N. Das Gupta), 83
Energy : Atomic, 609, 768
  Atomic, an International Responsibility, 153
  (Atomic) : Advisory Committee on, 262
  (Atomic) : Three-Power Declaration on, 615
Energy Generation in the Sun : Nuclear (N. R. Sen and U. R. Burman), 305
Energy Regulators (Sunvic Controls, Ltd.), 167
Energy Spectrum of Mesotrons at Low Energies (S. K. Ghosh and N. N. Das Gupta), 83
Energy Transfer in Chemical Reactions (Prof M. G Evans), 639
Energy of the Hg—C Bond and the Heat of Atomization of Carbon (Prof. N. V. Sidgwick and H. D. Springall), 599
Engineering : Aeronautical, at Bristol, 43
  Chemical, at the University of Leeds, 659
Engineering at the Imperial College : The City and Guilds College—(Prof. E F. D. Witchell), 650
Engineering at Queen Mary College, London, 137
Engineering and Optical Equipment (Precision) . Coventry Gauge and Tool Co., Ltd , Taylor, Taylor and Hobson, Ltd , and E. R. Watts and Son, Ltd., to co-operate in the development and distribution of, 387
Engineering and Science : Research Fellowships in, 659 .
Engineers : British Electrical, and the War (Dr. P. Dunsheath), 482
  Training of (Prof. Andrew Robertson), 775
England : Witchcraft in (Christina Hole), *review*, 765
  (South of) : Records of *Culex* (*Barraudius*) *modestus* (Diptera, Culicidæ) obtained in the (John F. Marshall), 172
England during the War : Colorado Beetle in, 776
England and Wales · Care of Geological Features in, 485
English Plants (Familiar)   A Flora of, *review* by Prof. F. J. Lewis, 461
Entry of Contact Insecticides : Mode of (W H. Potts and F. L. Vanderplank), 112 ; (Dr. N. E. Hickin), 753
Enzyme Activity as a Factor in Insect Physiology and Toxicology (Dr. H. Hurst), 194
Enzyme Protein · | Cell Proliferation, Carbohydrate Breakdown and Hydration of (Dr. A. Lasnitzki), 398
Enzyme System from Ischæmic Muscle : Synthesis of Adenosine Triphosphate by an (Marian Bielschowsky and Prof. H. N. Green), 117
Enzyme and Immune Reactions : Comparison of, *review* by Dr. P. Johnson, 517
Enzymes on Solid Nucleic Acid : Adsorption of (Dr. J. A. V. Butler), 781
Enzymes (Proteolytic) : Congo Red Fibrin Powder for Experiments on (D. G. Duncan and Dr. H. Zwarenstein), 112
Enzymology and related Subjects of Biochemistry : Advances in (edited by F. F. Nord and C. H. Werkman), Vols 4 and 5, *review* by Dr. J. H. Quastel, 611
Eosinophils and Pseudo-eosinophils of Rabbits' Blood : Differentiation between, by means of a Peroxidase Reaction (Dr F. Jacoby), 420
Ephemerides for the Determination of Time Corrections by Equal Altitudes (Zinger's Method) for 1944 (Astronomical Institute of the Academy of Sciences of the U.S S.R.), 16
Equatorial Regions : The Soils of, with special reference to the Netherlands East Indies (Prof. Dr. E. C. Jul. Mohr), translated from the Nederlandsch by Robert L. Pendleton, *review* by Dr. A Muir, 93
Ergot on *Pennisetum Hohenackeri* Hochst. (Prof. M. J. Thirumalachar), 754
Ergot in the Tropical Plains of Bengal : Artificial Production of (J. C. Saha and S. K. Bhattacharjee), 363
Eros . Re-Observation of the Magnitudes of the Southern Compariso Stars for (R. H. Stoy and A Menzies), 179
Escherichia coli : A Thermostabile, Fungistatic Factor from (Sten Wiedling), 204
Ester Wax, a New Embedding Medium (Dr. H. F. Steedman), 121
Ethics · Science and (Prof John A Ryle), 619, 623
Euphorbia Extracts   Insecticidal Properties of (F L Vanderplank), 782
Europe . Germany and (Dr. F. Darmstaedter), *review* by Capt. Maurice Bruce, 551
  Scientific Affairs in, 576
  Scientific Rehabilitation in, 472
  (Central) . Poverty and Politics in, *review* by Capt. Maurice Bruce, 55[illegible]
  (Modern)   The Scapegoat in (Royal Anthropological Institute and the Social Psychology Section of the British Psychological Society discussion on), 380
European Agriculture (United Nations Relief and Rehabilitation Administration), 15
European Broadcasting : Wave-lengths for, 250
Evolution . Animal Learning and (Dr. W H Thorpe), 46
  Tempo and Mode in (George Gaylord Simpson), *review* by Dr. Julian S Huxley, 3
Evolutionary Biology and related Subjects in the U.S S R. (Dr. Julian Huxley), 254 ; *errata*, 293
Evolutionary Change (Major) : Genetics and, *review* by Dr Julian S. Huxley, 3
Excavations at Hyrax Hill, Nakuru, Kenya Colony, 1937–1938 : Report on the (Mary D. Leakey), 722
Exchanges of Inorganic Ions through the Surfaces of Living Cells and through Living Membranes Generally . The Active and Passive (Prof August Krogh), 542
Excitors : Conditioned, and Human Sense Organs (Prof. Krikor Kekcheyev), 573
Experience of Time and its Lapse Rate : The Fitzgerald Contraction as the Origin of our (Prof. W. Peddie), 336
Exploded Wire : Spectra of Diatomic Oxides by the Method of (B. Rosen), 570
Exploration : Archæological, in South Africa (Prof. D M. S. Watson), 55
Explosives . The Science of (Prof Martin Meyer), *review* by Prof. John Read, 5
Exposure Cracking · The Mechanism of (Dr R. G. Newton), 10
Eye : A Pathology of the (Eugene Wolff), second edition, *review*, 279
  (Dark-adapting) · Absolute and Differential Light Sensitivity of the (Dr. H. Pollak and D. G. Wilson), 299
  (Living) : Measurement of the Diameters of the, by means of X-Rays (Prof Arnold Sorsby and A. D. O'Connor), 779

FAITHS of Many Lands (E. Royston Pike), *review* by Enid Blyton, 34
Familial Susceptibility to Tuberculosis (Dr. Ruth Rice Puffer), *review*, 19[illegible]
Family : The Needs and Problems of the (British Social Hygiene Council and the Town and Country Planning Association conference on), 777
Family Food Consumption in the United States (Miss M W Grant), 441
Fantasy as a Clinical Technique   Interpretation of, *review* by Dr. John Cohen, 701
Far East : Air Photography in the (Dr. V. J. Chapman), 604
  British Army Veterinary Services in the (Dr. G. Lapage), 60
Farm Accounting . Good (A. C. Campbell), *review*, 764
Farm Animals : Physiology of (Dr. F. H. A Marshall and E. T. Halnan), third edition, *review* by Dr. John Hammond, 377
Farmer (Woman) · Experiences of a, *review* by Sir John Russell, 280
Farmers · Accounting for, *review*, 764
Fatty Acids : Lubrication of Metal Surfaces by (Dr. F. P. Bowden, J. N. Gregory and Dr. D Tabor), 97
Fatty Constituents of Tubercle Bacilli as Growth-Inhibitors of the same Bacilli (Dr. Ng. Ph. Buu-Hoï), 392
Faulenseemoos bei Spiez : Pollenanalytische, stratigraphische und geochronologische Untersuchungen aus dem (Max Welton), 383
Faults in Low-Voltage Cables : Localization of (J. H. Savage), 201
Fauna and Flora of South Africa (Intertidal) . The Constitution of the (Prof. T. A. Stephenson), Part 2, 27
Fellmongering : Scientific Study of (Dr. D. Jordan Lloyd), 483
Fellowships · British Cotton Industry Research Association, 200, 686
Fellowships for Scientific Research in India, 107
Fermentation and Human Nutrition (Dr. B. S. Platt), 87
Fermented Foods (African) : B Vitamins in (Dr. Leon Golberg, J. M. Thorp and Sheila Sussman), 364
Ferns . An Experimental Treatment of the Apical Meristem in (Prof. C. W. Wardlaw), 39
Ferret . Enamel Cuticle (Nasmyth's Membrane) and Tartar Deposition in the (Dr. J. D. King), 572
Ferrier Lecture (Dr. Gordon Holmes), 201
Fertilizers in Britain : Use of, 776
Fertilizers during the War and After (Dr. E M Crowther), 776
Feulgen Reaction : Mechanism of the (J. G. Carr), 143
Fibres (Biological) . Structure of, and the Problem of Muscle (Dr W . T. Astbury), 89
Fibres (Nerve) . Structure, Degeneration and Repair of (J. Z. Young), 132
Fibres (Wool) · Frictional Properties of (M. Lipson), 268
  Scaliness of (J. Menkart and Prof. J. B Speakman), 143
Fibrin : Transition of Fibrinogen to, as a Two-Step Reaction (Dr. K. Laki and Dr. W. F. H. M. Mommaerts), 664
Fibrin Powder . Congo Red, for Experiments on Proteolytic Enzymes (D. G. Duncan and Dr H. Zwarenstein), 112
Fibrinogen to Fibrin as a Two-Step Reaction · Transition of (Dr. K. Laki and Dr. W. F. H. M. Mommaerts), 664
Field Biology . Middle East, 532
Film as an Instrument of Scientific Research (Derek Stewart), 426
Film in Science (Scientific Film Association conference on), 79, 426
Film (Scientific) : Teaching by means of the (J. Maddison), 57
Film Production (Basil Wright), 426
Film Strip in Technical Training (H. Richmond), 426

Film-Strip Projector : A New (Dufay-Chromex, Ltd.), 264
Films (Thin Metallic) : Resistivity of (Prof. A. Van Itterbeek and L. De Greve), 634
Filters (Percolating Sewage) : Control by D.D T. of Flies Breeding in (T. G. Tomlinson), 478
Finland . Recent Biological Work in (Dr G. H. Beale), 357
Fireside Deposit from an Economizer : Occurrence of Boron Phosphate in (L. M. Clark and J. Haslam), 302
Fischer-Tropsch Synthesis : Chromium Oxide as a Promoter in Catalysts for the (Sir J. C. Ghosh and S. L. Sastry), 506
Fish after a Major Injury : Survival of a, 714
Fish from New Jersey (Apogonid) · Description of a New Genus and Species of (Henry B. Fowler), 395
Fishes : Marine Cottid, of California (Rolf L. Bolin), 395
  New Genera and Species of, 395
  (Archaic) : Completion of the Bashford Dean Memorial Volume on (Dr. E. W. Gudger), 533
Fishes and Fisheries : Indian (Dr. Sunder Lal Hora), 511
'Fissibactericidal' Nature of Penicillin Action (Dr. S. W. Lee, E J. Foley and E. R. Caley), 49
Fitzgerald Contraction as the Origin of our Experience of Time and its Lapse Rate (Prof. W. Peddie), 336
Flagellates . Autotrophic, as the Major Constituents of the Oceanic Phytoplankton (Dr. W. R. G Atkins), 446
Flames (Coal Gas) : Influence of Sulphur Oxides on the Luminosity of (Dr. G. Whittingham), 207
Flavelle Medal of the Royal Society of Canada awarded to Prof. R. B Thomson, 271
Flax · Control of Foot Rot (*Phoma* sp) of (A E Muskett and J. Colhoun), 538
Fleas . A Simple Trap for Catching (A. H. Al-Hussaini), 501
Flies Breeding in Percolating Sewage Filters : Control by D.D.T. of (T. G. Tomlinson), 478
Flight of Bats · Acoustic Control in the (Prof. H. Hartridge), 490, 692 ; (A. J. Wilmott), 687 ; (Dr. D. W. Ewer), 692 ; (Flight-Sergt. Martin Wilkinson), 693
Flora of Familiar English Plants, *review* by Prof F J. Lewis, 461
Flora of South Africa (Intertidal Fauna and) · The Constitution of the (Prof. T. A. Stephenson), Part 2, 27
Flow of Water through Very Narrow Channels and Attempts to Measure Thermomechanical Effects in Water (Dr. J. Reekie and J. Aird), 367
Flowering of Horse-Chestnut : Late (Dr. Julian Huxley), 574 ; (Miss E M Blackwell), 721 ; (Dr. H. G. Baker), 721
Flowers · Common Wild (John Hutchinson), *review* by Prof F. J. Lewis, 461
Fluorescence of Dipropyl Ketone at Low Temperatures (Dr. S C. Sirkar and B. M Bishui), 333
Fluorescence Microscopy of Tubercle Bacilli (Dr. B. Juricic, Sr. Nicolás Vuskovic, Dr. Gastón González, Dr. Hernán Durán and Dr. Hipólito Vergara), 16
'Fly's Eye' : X-Ray Analysis with the Aid of the (Sir Lawrence Bragg and A. R. Stokes), 332
Foie : A propos d'un procédé d'exploration simple de l'état fonctionnel du (J. Bailly and G. Decrop), 395
Folk-Lore of Toothache (Dr. J. D. Rolleston), 387
Fonctions : Théorie des (Prof. Georges Valiron), *review* by Prof. H. T H. Piaggio, 648
Food (Minister of) · If I were, in Peace-time (Sir John Boyd Orr), 292
Food for Cattle · Use of Trees and Shrubs as, 151
Food Consumption : Family, in the United States (Miss M. W. Grant), 441
Food Intake · Effect of Restriction of, upon the Incisor Teeth of Rachitic Rats (Prof. J T. Irving), 664
Food Policy in Britain, 292
Food Science, *review* by Dr T. Moran, 220
Food and Food Products : The Chemistry and Technology of (edited by Dr. Morris B. Jacobs), Vol 2, *review* by Dr. T. Moran, 220
Foods (African Fermented) : B Vitamins in (Dr. Leon Golberg, J. M. Thorp and Sheila Sussman), 364
Foods (Proteins and) : The Amino Acid Composition of (Dr. Richard J. Block and Diana Bolling), *review*, 33
Foods (War-time) : Nutritive Values of (Medical Research Council War Memorandum No. 14), 330
Foot Rot (*Phoma* sp.) of Flax : Control of (A. E. Muskett and J. Colhoun), 538
Foreign Policy : Science and (G. Fielding Elliot), 63
Forest Policy in India . Post-War (Prof. E. P. Stebbing), 286
Forestry Economy of Madras : Agricultural and (J A Wilson), 151
Forestry Problems in the United States, *review* by Prof. F. J Lewis, 584
Forests : The Hazel Period in the Post-Glacial Development of (Prof. Felix Rawitscher), 302
Forests of New Zealand . Indigenous (Prof. E. P. Stebbing), 60
Fourier Systems · Accuracy of Atomic Co-ordinates Derived from (A. D Booth), 51
Fourier Transformer . A Photo-Electric (Prof. Max Born, Dr. R. Furth and R. W. Pringle), 756
Fovea Centralis : Colour Sensitivity of the (E. N. Willmer and W. D. Wright), 119
Fowl : An Induced Carcinoma in the (F. Bielschowsky and Prof. H. N. Green), 780
France : Reorganization of Museums in, 641
Franklin Medal Lecture on Atomic Energy as a Human Asset (Dr. Arthur H. Compton), 687
Fredericq (Léon) et les débuts de la physiologie en Belgique (Prof. Marcel Florkin), *review* by Prof. C. Lovatt Evans, 764
Freedom of Scientific Intercourse, 215
Freedom for Scientific Research (Lord Brabazon of Tara), 746
French and German Geographical and Geological Institutions : Some (Dr. John W. Wells), 243
Frictional Properties of Wool Fibres (M. Lipson), 268
Friedel-Crafts Catalysts in Carbon-Monoxide Reactions (Dr. P. H. Sykes), 638
Friedel-Crafts Catalysts and Polymerization (Department of Chemistry, University of Manchester conference on), 232, 638
Frost · Use of Growth-Promoting Substances in the Prevention of Apple Drop following (T. Swarbrick), 691
Frost Injury Simulating Virus Disease Symptoms on Potato Foliage (Robert McKay and Dr. Phyllis E. M. Clinch), 449
d-Fructofuranose and *d*-Glucose : Yeast Hexokinase and its Substrates (Dr. A. Gottschalk), 540
Fruit Growers' Conferences · Vegetable and (edited by Dr. D H. Robinson), *review*, 489
Fruit Storage and Transport : Use of Carbon Dioxide in (F. Gerhardt, E. Smith and H. English), 178 ; (A. V Doreen, M. B Hoffman and R. M. Smock), 178 ; (F. W Allen, W. T. Pentzer and C. O. Bratley), 178 ; (W. T. Pentzer and F. W. Allen), 178
Fruit Trees : Phosphorus Deficiency of (L. R. Bryant and R. Gardner), 178
  Root Distribution of (E. L Proebsting), 395
Functional Condition of the Liver Examining the, 395
Functions of a Complex Variable, *review* by J. H. Pearce, 67
Fungi : Trees and, *review*, 732
Fungi in Wareham Heath Soil . Origin of Toxicity to (Dr. M. C. Rayner), 174
Fungistatic Factors : A Thermostabile, from *Escherichia coli* (Sten Wiedling), 204
Fungistatic Substance ·, Viridin, a Highly, produced by *Trichoderma viride* (Dr. P. W Brian and J. C. McGowan), 144
Funktionen (elliptische) : Vorlesungen uber allgemeine Functionentheorie und (Prof Adolf Hurwitz), dritte auflage, *review* by J. H. Pearce, 67
Funktionentheorie und elliptische Funktionen : Vorlesungen uber allgemeine (Prof Adolf Hurwitz), dritte auflage, *review* by J. H. Pearce, 67
Fusarium oxysporum cubense : Inhibition of the Development of, by a Growth Substance produced by Meredith's Actinomycetes (Dr. A. C. Thaysen and K R. Butlin), 781

GARDEN Birds (Phyllis Barclay-Smith), *review*, 34
Garden Book . Thomas Jefferson's, 1766–1924, with Relevant Extracts from his other Writings (annotated by Prof. Edwin Morris Betts), *review* by Dr. E. J. Salisbury, 128
Garden Gate : Through my (Newman Flower), *review*, 614
Gases : Effect of Pressure on Thermal Diffusion in (K E. Grew), 267
  (High-Pressure) Afterglow Effects in (Dr. J. D Craggs and Dr. J. M. Meek), 21
  (Hot) : Production of Skin Burns by (O. M. Lidwell), 298
  (Inert) : The Spectral Structure of the (Prof. Bengt Edlén), 445
Gastric Mucosa · A Theory of the Formation of Hydrochloric Acid in the (Prof. E J Conway, O. FitzGerald and D Watts), 477
Geddes, Patrick (Philip Boardman), *review* by R. Brightman, 612 ; *erratum*, 687
Geiger-Muller Counter (Fast) · Effect of the Pressure of Alcohol Vapour on the Operation of the (Dr. G. D Rochester and C. B. A. McCusker), 366
Genetic Types of Manganese Deposits (Prof Arthur Holmes), 87
Genetics and Major Evolutionary Change, *review* by Dr. Julian S. Huxley, 3
Geographer as Humanist (Prof. W. Fitzgerald), 355
Geographical and Geological Institutions : Some French and German (Dr. John W. Wells), 243
Geography in New Zealand, 44
Geological Features in England and Wales : Care of, 485
Geological Institutions (Geographical and) : Some French and German (Dr John W. Wells), 243
Geological Survey (Colonial) . The Contribution of, to the Development of the Mineral and other Resources of East and West Africa (Sir Edmund Teale), 167
Geology of the Nubian Sandstone (Dr. N M. Shukri), 116
Geology and Palæobotany in the U S S.R (W. N. Edwards), 282
Geometrische Funktionen : Abschnitt uber (Prof. R. Courant), *review* by J. H Pearce, 67
Germ Cells in Teleosts · Sexual Differentiation of the Gonad and the Sexualization of the (Prof. Umberto D'Ancona), 603
German Economic Sphere . The Danube Basin and the (Dr. Antonin Basch), *review* by Capt. Maurice Bruce, 551
German Geographical and Geological Institutions : Some French and (Dr. John W Wells), 243
German Men of Science to be taken to the United States, 445
German Military Maps (Royal Geographical Society exhibition of), 445
German Occupation : Bread in Jersey during (Dr. D. W Kent-Jones and Dr. A. J. Amos), 336
German University in Prague : Closing of the, 502
Germany : The Regions of (Dr. Robert E. Dickinson), *review* by Prof. W. Fitzgerald, 253
Germany and Europe (Dr. F. Darmstaedter), *review* by Capt. Maurice Bruce, 551
Germany and Japan : The Control of (Dr. Harold G. Moulton and Dr. Louis Marlio), 64
Germination of Bearded Iris Seeds (L. F. Randolph and L G. Cox), 395
Giant's Causeway : The (Prof. Arthur Holmes), 425
Gigartina stellata : A Polysaccharide from—the Isolation of Crystalline 2 : 6-Dimethyl-*β*-*d*-Galactopyranose from the Methylated Polysaccharide (Eric T. Dewar and Dr. E. G V Percival), 633
Glacial Times : Lowering of Sea-Level in (A. Farrington), 396
Glass · Strength of, and Duration of Stressing (F. W. Preston), 55
Glass Houses : People Who Live in (A V D. Orderly), 501
Glasses : The Bates Method for Good Sight without (Dr. William H. Bates), *review*, 281
Glide in Metal Single Crystals · Effect of Alpha-Ray Bombardment on (Prof. E. N. da C. Andrade), 113
Glioma in a Rat Fed with 2-Acetyl-amino-fluorene (Dr. E. Vazquez Lopez), 296
Glow Discharge · Visible, at Very Low Potentials (Dr. A Sommer), 242
d-Glucose : Yeast Hexokinase and its Substrates *d*-Fructofuranose and (Dr. A. Gottschalk), 540
Glue : Wood and (Dr. M. C. Pryor), 306
Glycerides of Rape (*Brassica napus* L.) Leaf : Occurrence of Hexadecatrienoic Acid in the (Dr. F. B. Shorland), 269
God : Science and the Idea of (William Ernest Hocking), *review*, 281
Gonad : Sexual Differentiation of the, and the Sexualization of the Germ Cells in Teleosts (Prof. Umberto D'Ancona), 603
Gonadal Hormones : Relation of the, to certain Dermatoses (Dr. Georges Garnier), translated by Major James Marshall, 339

Good and the Clever The (Master of Balliol), 744
Government Control in War (Lord Hankey), 457
Government Scientists A New Deal for, 644
Government Support for Research Associations in Britain (Herbert Morrison), 597
GR-S : The Behaviour of Natural Rubber and, under Repeated Stress Cycles (Dr. D. Parkinson and J L. Bloxham), 11
  Weathering of (H. C. Harrison), 10
GR-S Vulcanisates : The Heat Ageing of (Dr J. R. Scott), 10
Gram-positive Complex in Micro-organisms · Nature of the (Dr. H. Henry, Dr. M Stacey and Dr Ethel G. Teece), 720
Granules of the Human Polymorphonuclear Leucocyte (Major J. F. A. McManus), 173
Grass : Thatch (Dr. B. C. Sharman), 342
  (Dried) Determination of β-Carotene in (T. Barton Mann and W. M Seaber), 571
Grasses · Californian Marine Algæ and, 533
Gravitation : A Classical Theory of Electromagnetism and (Dr. H. C. Corben), 388
  The Two-body Problem in Milne's Theory of (G. J. Whitrow), 365
Great Britain Dental Teaching and Research in (Nuffield Foundation to make grants for), 417
  Industrial Research in, 711
  Medical Films in (Royal Society of Medicine in co-operation with the Scientific Film Association to prepare a catalogue of), 387
  Penicillin Production in, 386
  The Recruitment and Training of Plant Pathologists in (Association of Applied Biologists), 724
  Research in Animal Breeding and Genetics in, 231
  The Teaching of Analytical Chemistry in, with special reference to Microchemistry (Dr Cecil L. Wilson), 588
  See *also under* Britain
'Green Flash' at Sunset with a near 'Horizon' (D. R. Barber), 146 ; (Dr. C. E. P. Brooks), 368
Green Mansions : Behold our (Richard H D. Boerker), *review* by Prof. F. J. Lewis, 584
Growth *in vitro* of Acid-fast Bacteria · Inhibitory Action of Dialkyl Succinic Acid Derivatives on the (Vincent C. Barry and Dr. P. A. McNally), 48
Growth of Bone : Recent Investigations on the (Prof. P Lacroix), 576
Growth-Factors and Growth Inhibitors for Micro-organisms (Dr. B. C. J. G. Knight), 86
Growth Inhibition in Pea Seedlings (E. Dorothy Brain), 397
Growth Inhibitors : Growth-Factors and, for Micro-organisms (Dr. B. C J. G Knight), 86
Growth-Inhibitors of the same Bacilli : Fatty Constituents of Tubercle Bacilli as (Dr. Ng. Ph Buu-Hoï), 392
Growth-Promoting Substances in the Prevention of Apple Drop following Frost : Use of (T. Swarbrick), 691
Growth Substance produced by Meredith's Actinomycetes : Inhibition of the Development of *Fusarium oxysporum cubense* by a (Dr. A C. Thaysen and K. R. Butlin), 781

HAEM-AGGLUTININS (Immune) . Enhancement of the Action of, by Human Serum (K. E. Boorman, B. E Dodd and Dr. W. T. J. Morgan), 663
Hæmocyanin Molecules · Electron Shadow-Micrographs of (Prof. Robley C. Williams and Dr. Ralph W. G. Wyckoff), 68
Hæmoglobin in Blood-sucking Parasites (Prof. H. Munro Fox), 475
Hæmoglobins . Individual (Prof. H. Munro Fox), 18
Hæmolytic Substance . Crystalline, from Normal Blood (Dr. H. Laser and Dr E. Friedmann), 507
Halides · The Catalytic (Dr. F. Fairbrother), 638
  (Catalytic) : The Molecular Structure of the (Dr. H. A. Skinner), 638
Halogenation in the Allyl Position (Dr. William E. Vaughan, Frederick F. Rust and George W. Hearne), 53 ; (Dr. W. A. Waters), 53
Hamsters infected with *Leishmania* : Œdema in (L. G. Goodwin), 476
Haploid-Diploid Twin Embryos in Angiosperms : Origin of (Dr. P. Maheshwari), 173
Harmonics in the Piezo-Electric Oscillation of a Quartz Crystal (L. C. Tsien and H. C. Chu), 424
Harmonics (Spherical) : The Theory of Potential and (Wolfgang J. Sternberg and Prof. Turner L. Smith), *review* by J. H. Pearce, 5
Hartley (Marcellus) Public Welfare Medal for 1945 of the United States National Academy of Sciences awarded to Dr. Vannevar Bush, 575
Harvest : Four Years (Frances Donaldson), *review* by Sir John Russell, 280
Hatching of the Egg of *Ixodes ricinus* L. (D. R. Arthur), 538
Hay-fever Plants (Roger P. Wodehouse), *review* by Dr. H. Godwin, 317
Hazel Period in the Post-Glacial Development of Forests (Prof. Felix Rawitscher), 302
Healing : British Achievement in the Art of (John Langdon-Davies), *review* by Dr. G. Lapage, 350
Health : The Animal in, *review* by Dr. John Hammond, 377
Health Research in Industry (Dr. G. Lapage), 148
Health and Disease : The Child's Blood in, *review* by Prof. Thos. B. Davie, 192
Heart : Transplantation of the (Prof. Nikolai Sinitsin), 536
Heat : A Text-Book of (G. R. Noakes), *review*, 377
Heat of Atomization of Carbon : Energy of the Hg—C Bond and the (Prof. N. V. Sidgwick and H. D. Springall), 599
Heat Ageing of GR-S Vulcanisates (Dr. J R. Scott), 10
Heat Coagulation of Muscle Proteins (Dr. E. C. Bate-Smith and J. R. Bendall), 632
Heat Injury in Insects (G. T. Jefferson), 111
Heaviside's Operational Calculus Made Easy (Dr. T H. Turney), *review* by Dr. L. E. C. Hughes, 6
Helminths : A Medium for Mounting Parasitic (Dr. Fei-pai Li and Fu-si Yang), 297 ; (Dr. G. Lapage), 298
Helvolic Acid : Activity of, against *Mycobacterium tuberculosis* (M. A. Jennings), 633
Hen : Life-Cycle of the Red Corpuscles of the (Prof. G. Hevesy and J. Ottesen), 534
Heterogeneity of Human Serum Albumin (H. Hoch and C. J O. R. Morris), 234
Heterokaryosis and the Mating-Type Factors in *Neurospora* (Eva Sansome), 47
Hexachlorocyclohexane as an Insecticide (L. B. Bourne), 85 ; (Sidney Rogerson), 424
Hexadecatrienoic Acid in the Glycerides of Rape (*Brassica napus* L.) Leaf : Occurrence of (Dr. F. B. Shorland), 269
High Polymer Bulletin . Publication of a, 167
High-Pressure Gases : Afterglow Effects in (Dr. J. D. Craggs and Dr. J. M. Meek), 21
Highland Year A (Seton Gordon), *review* by Dr. F. Fraser Darling, 219
Histological Fixation of Locomotory Patterns (H. W. Lissmann), 391
Histological Sections : Double-Refringence of the Amyloid-Congo-Red-Complex in (Dr. Peter Ladewig), 81
Histology : Morbid, of the Eye, *review*, 279

Imperata cylindrica (Imperial Agricultural Bureaux Joint Publication No. 7), 342
Imperial Chemical Industries Fellowships at Cambridge, 17
Imperial College : The City and Guilds College—Engineering at the (Prof. E. F. D Witchell), 650
  Physics and Astrophysics at the (Prof. Herbert Dingle), 562

Inactivation : Anomalous, of Heavy Metal Antifouling Paints (Prof John E. Harris), 206
Incisor Teeth of Rachitic Rats : Effect of Restriction of Food Intake upon the (Prof. J. T. Irving), 664
Indexes of Data for Identification Purposes (Dr. A. F. Wells), 535
India : Fellowship for Scientific Research in, 107
  National Physical Laboratory for, 15
  Peoples of (Wm. H. Gilbert, jr.), 292
  Post-War Forest Policy in (Prof. E. P. Stebbing), 286
  Science and Education in, 291
  Symposium on, *review* by Prof J H. Hutton, 66
India and the British Colonies : Scientific Research in, 758
Indian Fishes and Fisheries (Dr. Sunder Lal Hora), 511
Indian Plywood Tea Chests : The Testing of (V. D. Limaye), 668
Individual Hæmoglobins (Prof. H Munro Fox), 18
Indoamericanismo y el Problema Racial en las Américas (Prof. Dr. Alejandro Lipschutz), segunda edicion, *review* by Prof. A. R. Radcliffe-Brown, 158
Indology and Oriental Culture (Royal Asiatic Society of Bengal conference on), 687
Industrial Research Bill, 625, 711
Industrial Research in Great Britain, 711
Industry : Health Research in (Dr. G. Lapage), 148
  Morale in, 91
  Some Problems of the Special Librarian in (E. N Simon), 605, 606
Industry in Australia : The Application of Science to (Sir David Rivett), 472
Industry (Scientific Instrument) : Man-Power and Training in the, 154
Inert Gases : The Spectral Structure of the (Prof. Bengt Edlén), 445
Infant's Mind : Measuring the, *review* by Dr John Cohen, 349
Inferiority Complex and the Paranoid Tendency, with a Brief Reference to Nazi Psychology (Dr. William Brown), 259
Information Service as an Essential in the Progress of Science (Prof. J. B. Bernal), 605
Infra-red Absorption : Chemical Analysis and Structural Diagnosis by, *review* by Dr. H. W. Thompson, 65
Infra-red Spectra of Coals (C. G. Cannon and Dr. G. B. B. M. Sutherland), 240
Infra-red Spectra of Rock-salt : Raman and (Dr. R. S. Krishnan), 267
Infra-red Spectroscopy (R. Bowling Barnes, Robert C. Gore, Urner Liddel and Van Zandt Williams), *review* by Dr. H. W. Thompson, 65
Infra-red Spectrum of Diamond (K. G. Ramanathan), 23
Infra-red Spectrum of the Night Sky (R. Herman, L. Herman and J Gauzit), 114
Inheritance of Melanism in Grey Squirrels (Monica Shorten), 46
Inheritance and Acquired Characteristics (Prof. Wm. Rowan), 236
Inhibition of the Development of *Fusarium oxysporum cubense* by a Growth Substance produced by Meredith's Actinomycetes (Dr. A. C. Thaysen and K. R Butlin), 781
Inhibitory Action of Dialkyl Succinic Acid Derivatives on the Growth *in vitro* of Acid-fast Bacteria (Vincent C. Barry and Dr. P. A. McNally), 48
Injury : Heat, in Insects (G T. Jefferson), 111
  (Major) : Survival of a Fish after a, 714
Innes (John) Horticultural Institution, 586
Inorganic Ions : The Active and Passive Exchanges of, through the Surfaces of Living Cells and through Living Membranes Generally (Prof. August Krogh), 542
Inorganic Salt Solutions : Cytological Reactions Induced by (Albert Levan), 751
Insect Physiology and Toxicology : Enzyme Activity as a Factor in (Dr. H. Hurst), 194
Insect Punctures (*Dysdercus* sp.) : Control of Internal Boll Rot of the Cotton Plant, caused by, through Selection of Resistant Strains (Prof. Teodoro Boza Barducci, Prof. Germán García Ráda and Prof. Johannes Wille), 235
Insect and Plant Pests . Biological Control of (Dr. W R. Thompson), 271
Insecticidal Action of D D.T. (J. R. Busvine), 169
Insecticidal Properties of *Euphorbia* Extracts (F. L. Vanderplank), 782
Insecticide . Hexachlorocyclohexane as an (L. B. Bourne), 85 ; (Sidney Rogerson), 424
Insecticides, 168
Insecticides (Contact) : Mode of Entry of (W. H. Potts and F. L. Vanderplank), 112 , (Dr. N. E. Hickin), 753
Insects . Heat Injury in (G. T. Jefferson), 111
Instability of Dienœstrol and Stilbœstrol Solutions (A. E. Wilder Smith and P. C. Williams), 718
Instrument Jewels and Pivots : Meter and (G. F. Shotter), 89
Instruments : Moving-Coil (G. F. Tagg), 396
Integration . Compromise and (Colonel L Urwick), 93
Intelligence Tests for Young Children (Prof. C. S. Valentine), *review* by Dr. John Cohen, 349
Interfaces . Reactions at, and their Significance in Biology (Dr. J. F. Danielli), 468
Interfacial Tension and Density *in* Solutions : Time Dependence of (Prof. George Antonoff), 301
Interference Effect : A New (F. K. Bauchwitz and D. Shoenberg), 142
International Collaboration, 78
International Co-operation in Social and Economic Fields, 231
International Labour Office . The New (British Association for Labour Legislation), 231
International Morality : The Problems of Education in (United Nations Fellowship discussion on), 444
International News, Bulletin of . To be replaced by *The World To-day*, 167
International Science Co-operation Service, 401
International Scientific Commission : A Permanent (Prof. J. D. Bernal), 557
International Scientific Co-operation in Post-War World Organisation : The Place of Science and (Dr. Joseph Needham), 558
Interpretation of Fantasy as a Clinical Technique, *review* by Dr. John Cohen, 701
Inverse Binomial Sampling (Dr. R. A. M Case), 115
Iodine : Emission Bands of the Fluctuation Type in the Spectrum of (Prof. R. K. Asundi and P. Venkateswarlu), 452
Ionic Migration In Molten Salts : Activation Energy of (Dr. E. Heymann and H. Bloom), 479
Ions and Dipolar Ions : Proteins, Amino-Acids and Peptides as (Edwin J. Cohn and John T. Edsall), *review* by Dr. Kenneth Bailey, 405
Ions (Inorganic) : The Active and Passive Exchanges of, through the Surfaces of Living Cells and through Living Membranes Generally (Prof. August Krogh), 542
Ireland : Occurrence of the Diphyllobothriidæ in (J R. Harris and Dr. M. D. Hickey), 447
Iris Seeds (Bearded) : Germination of (L. F. Randolph and L. G. Cox), 395
Irish Rivers : Previously Spawned Salmon In (Arthur E. J W ent), 178
Iron in Peroxidase : Can the, be Replaced by Manganese ? (Prof. Hugo Theorell), 474
Iron Age (Early) A Find of the, from Llyn Cerrig Bach, Anglesey (Sir Cyril Fox), 309
Iron Age Finds from Anglesey (M. C. Burkitt), 309
Ischæmic Muscle : Synthesis of Adenosine Triphosphate by an Enzyme System from (Marian Bielschowsky and Prof. H. N. Green), 117
Isle of Wight : Earthquakes recorded by E. W. Pollard, during March, 79 ; during April and May, 201 ; during June, 545 ; on November 27, 712
Isoclinics in Photo-elastic Methods : A Photographic Method of deriving (B. Dunn), 480
Isomeric Mepacrines (Optically) : Properties of (Prof. G. F. Gause), 784
Ixodes ricinus L. : Hatching of the Egg of (D. R. Arthur), 538

JAMAICA : Nutrition In, 288
Japan (off the coast of) : Earthquake on January 12, 79 ; on February 10, 79
Japan (Germany and) : The Control of (Dr. Harold G. Moulton and Dr. Louis Marlio), 64
Jefferson's (Thomas) Garden Book, 1766—1824, with Relevant Extracts from his other Writings (annotated by Prof. Edwin Morris Betts), *review* by Dr. E. J Salisbury, 128
Jersey during German Occupation . Bread in (Dr. D W. Kent-Jones and Dr. A J. Amos), 336
Jet Propelled Aircraft : Air Speed Record by (Group-Captain H J. Wilson), 597
Jewels and Pivots : Meter and Instrument (G. F. Shotter), 89
Jews and Medicine (Prof. Harry Friedenwald), *review* by Dr Walter Pagel, 31
Jones-Bateman Cup for original research in fruit culture (Royal Horticultural Society), 17
Journal of the Chinese Chemical Society : Volumes for the years 1941–44, 511
Journals : Books and, for Holland and Denmark, 263

KALA Azar : Penicillin in (Dr. E. S Horgan and Mohamed Hamed Satti), 297
Kamchatka : Volcanological Station at (V. I. Vlodavetz), 640
  (east of) : Earthquake on April 15, 201
Kaolinite . Structure of (Dr. G. W. Brindley and Keith Robinson), 661
Kew : Botanist for India at, 444
Kilimanjaro—Crater Fumaroles of Kibo and Seismic Activity during 1942–45 (J J Richard), 352

Lantern Slides of Line Drawings (Dr. G. D. Yarnold and L. Heath), 574
Larke (Sir William J), Medal of the Institute of Welding for 1945 awarded to W. K. B Marshall, 473
Latin America Plants and Plant Science in (edited by Frans Verdoorn), *review*, 676
Laue Photographs of Sub-crystalline Regions in 'Hybrid' Crystals of Potassium Dihydrogen Phosphate (Dr. A. R. Ubbelohde and Miss I. Woodward), 20
Lead Intensifying Screens : 'Electron Radiography' using Secondary β-Radiation from (H. S. Tasker and S. W. Towers), 50
Leaf : Physical Conditions of the Surface of the Mesophyll Cell Walls of the (Prof Francis J. Lewis), 407
Legume Nodule Bacteria . Effective and Ineffective Strains of (Dr. H. G. Thornton), 654
Leishmania : Œdema in Hamsters Infected with (L. G. Goodwin), 476
Leishmania Infections : Penicillin in (J D. Fulton), 203
Lend-Lease, Weapon for Victory (E. R. Stettinius), 78
Leucocyte (Human Polymorphonuclear) : Granules of the (Major J. F. A. McManus), 173
Libraries University and Research (Library Association conference on), 417
Library Technique (Special) : Manual of (J. E. Wright), *review* by R. Brightman, 406
(Lichtenberg Figures) : Electric Discharge on a Dielectric Surface (A. Morris Thomas), 451
Life : Low-Temperature Limits of (S. A Zernov and O. I. Schmalhausen), 304
Life of Woodlice : Duration of (Dr Walter E. Collinge), 755

- Life-Cycle of the Red Corpuscles of the Hen (Prof. G. Hevesy and J. Ottesen), 534
- Light Sensitivity : Absolute and Differential, of the Dark-Adapting Eye (Dr. H Pollak and D. G. Wilson), 299
- Lightning · Ball, 293
- Lignification : Abnormal, in the Wood of some Apple Trees (Dr. A. Beryl Beakbane and Dr. Eleanor C. Thompson), 145 ; *erratum*, 202
- Linnæus : A Recently Discovered Manuscript by (Dr. Anders Grape), 351
- Linoleic Acid : Autoxidation of (Sune Bergstrom), 717
- Liquid Metals : Electrical Resistance of (Prof. K. S. Krishnan and A. B. Bhatia), 503
- Liquids : Viscosity of Ordinary, at High Rates of Shear (L. Grunberg and Dr. A. H. Nissan), 241
- Liquids and Colloidal Solutions : Viscosity of (Academy of Sciences of the U.S.S R. conference on), 147
- *Lithobius forficatus* : Behaviour of the Common Centipede (Capt. J. L. Cloudsley-Thompson), 537
- Liver : Examining the Functional Condition of the, 395
- Livers of Pellagrins : Porphyrin Fluorescence in the, in relation to Ultra-Violet Light (Dr. J. Gillman, Dr. T. Gillman and S Brenner), 689
- Liversidge Lecture (Prof. E. K Rideal), 468
- Living Cells : The Active and Passive Exchanges of Inorganic Ions through the Surfaces of, and through Living Membranes Generally (Prof. August Krogh), 542
- Living Eye : Measurement of the Diameters of the, by means of X-Rays (Prof. Arnold Sorsby and A. D. O'Connor), 779
- Llyn Cerrig Bach, Anglesey : A Find of the Early Iron Age from (Sir Cyril Fox), 309
- Locomotory Patterns : Histological Fixation of (H. W. Lissmann), 391
- Locust (Desert) · Presence of Reddish Pigment in Eggs and Ovarioles of the, and its Probable Phase Significance (Dr. M. L. Roonwal), 19
- Locust Swarms in relation to Temperature . Mass Departure of (Dr. D L. Gunn, Flying-Officer F. C. Perry, Flight-Lieut. W. G. Seymour, Flight-Lieut. T. M. Telford, A.C.2 E N. Wright and D. Yeo), 628
- Logarithmic Scales (F. Campbell Rose), 268
- Lognormal Distributions (Prof. J. H. Gaddum), 463, 747 ; (Dr. Percival Allen), 746 , (S C. Pearce), 747
- Long-Wave Solar Radiation from Black-Body Intensity : Departure of (Sir Edward Appleton), 534
- Lord and Taylor Annual American Design Award for 1945 presented to the United States National Academy of Sciences, 575
- Low-Temperature Limits of Life (S. A. Zernov and O. I. Schmalhausen), 304
- Low Temperatures ,Fluorescence of Dipropyl Ketone at (Dr. S. C. Sirkar and B. M. Bishui), 333
- Lubrication of Metal Surfaces by Fatty Acids (Dr. F. P Bowden, J. N. Gregory and Dr. D. Tabor), 97
- Luminosity of Coal Gas Flames : Influence of Sulphur Oxides on the (Dr G. Whittingham), 207

- MACROSSAN (John Murtagh) Memorial Lectures (Sir David Rivett), 472
- Madras : Agricultural and Forestry Economy of (J. A. Wilson), 151
- Magendie, François—Pioneer in Experimental Physiology and Scientific Medicine in Nineteenth Century France (J. M. D. Olmsted), *review* by Prof. E. D. Adrian, 316
- Magnesium and its Alloys : Metallography of (Walter Bulian and Eberhard Fahrenhorst), translated by the Technical Staffs of F. A. Hughes and Co., Ltd., and Magnesium Elektron, Ltd., *review*, 614
- Magnetic Susceptibility of Molybdenite Crystals : Effect of Temperature on (Ajit Kumar Dutta), 240
- Magnetism : The Earth's (Prof. Sydney Chapman), 45
- Magnitudes of the Southern Comparison Stars for Eros : Re-Observation of the (R. H. Stoy and A. Menzies), 179
- Mammalian Striated Muscle · Regeneration of (Prof. W. E. Le Gros Clark), 109
- Mammary Cancer in Mice (Dr. E. Boyland), 787
- Mammary Tumours in Mice (Members of the Staff of the National Cancer Institute, United States Public Health Service), 787
- Man · Ecology in the Service of, *review* by Sir John Russell, 675
  - The Organisation of the Visual Cortex in (Dr Gordon Holmes), 201
  - Is the Progress of Science Controlled by the Material Wants of (Dr. F. Sherwood Taylor), 166
- Man and his Fellowmen (Dr. Samuel Lowy), *review* by Dr. J. Leycester King, 279
- Management of a Special Library, *review* by R. Brightman, 406
- Manganese ? : Can the Iron in Peroxidase be Replaced by (Prof. Hugo Theorell), 474
- Manganese Deposits : Genetic Types of (Prof. Arthur Holmes), 87
- Manganese Deposits of the U.S.S.R. (A. G. Betekhtin), 87
- Mankind : Medicine and (Arnold Sorsby), *review*, 129
- Man-Power and Training in the Scientific Instrument Industry, 154
- Man-Power and Resources (Scientific) : Committee on, 686
- Manuscript by Linnæus : A Recently Discovered (Dr. Anders Grape), 351
- Map of the British Isles, 16
- Maps : German Military (Royal Geographical Society exhibition of), 445
- Maps of Britain : National (Ministry of Town and Country Planning), 776
- Marine Algæ and Marine Grasses of San Diego, California : Annotated List of the (E. Yale Dowsen), 533
- Marine Cottid Fishes of California (Rolf L. Bolin), 395
- Marine Ecology in South Africa, 27
- Marine Hydrography : Ceratium and (Prof. F. E. Fritsch), 181
- Marine Organisms · Chemical Composition of (S. I. Tomkeieff), 607
- Matabeleland · Future of Electricity Supply in (A. R. Sibson), 168
- Material Wants of Man ? : Is the Progress of Science Controlled by the (Dr. F. Sherwood Taylor), 166
- Materials : Strength of (British Rheologists' Club conference on), 306
- Mathematics : Advanced, *review* by Prof. H. T. H. Piaggio, 648
  - (School) · A New Approach to, 330
- Mating-Type Factors in *Neurospora* : Heterokaryosis and the (Eva Sansome), 47
- Maturity (Mental) : The Concept of (Prof. A. W. Wolters), 494
- Measurement of High Voltages (Dr. J. M. Meek and F. W. Waterton), 422
- Measuring the Infant's Mind, *review* by Dr. John Cohen, 349
- Mechanical Test Results : Application of Statistical Methods to (Dr. B. Chalmers and E. R. W. Jones), 307
- Mechanism of the Beckmann Rearrangement (Flight-Lieut. Bryan Higman), 242 ; (M. J. S. Dewar), 688
- Mechanism of the Benzidine and related Rearrangements (M. J. S. Dewar), 784
- Mechanism of the Feulgen Reaction (J. G. Carr), 143
- Mechanism of Polymerization of Vinyl Compounds (Prof. H. W. Melville), 639
- Mechanization of Sugar Beet Production, 361
- Medical Exhibition . British, at the Sao Jose Hospital in Lisbon, 45
- Medical Films in Great Britain : Royal Society of Medicine in co-operation with the Scientific Film Association to prepare a catalogue of, 387
- Medical Research, Beit Memorial Fellowships for : Annual Report of the Trustees for the Year 1944–45, 140
  - Elections, 140
- Medical Research (Experimental) : Public Health and its Debt to (Sir William Savage), 417
- Medical Science : Achievement in, *review* by Dr. G. Lapage, 350
- Medicine . The Art of, in relation to the Progress of Thought (A. E. Clark-Kennedy), *review* by Dr. G. Lapage, 488
  - The Film in (Medical Committee of the Scientific Film Association discussion on), 426
  - The Jews and (Prof. Harry Friedenwald), *review* by Dr. Walter Pagel, 31
  - Nobel Laureates in, 533, 564
  - Travelling Fellowships in, 17
- Medicine in the United States : Practice of (Interim Report of the New York Academy of Medicine Committee on Medicine and the Changing Order), 341
- Medicine in the U.S.S.R. (Prof. Arnold Sorsby), 226
- Medicine and the Humanities, *review* by Dr. G Lapage, 488
- Medicine and Mankind (Prof Arnold Sorsby), *review*, 129
- Medicine (Biology and) : Direct Chemical Action upon Nerve Centres in (Prof. Lena Stern), 7
- Medium-Voltage Circuits : Over-Current Relays on (A G. Shreeve and P. J. Shipton), 305
- Melanin : A Neutral Solvent for (A. J. Lea), 478
- Melanism in Grey Squirrels . Inheritance of (Monica Shorten), 46
- Melanosis of Riehl-Poikiloderma (Cervico-Facial Pigmentation) (Dr. Georges Garnier), translated by Major James Marshall, 163
- Men who Habitually Squat : The Popliteal Facet in (Prof. M. A. Shah), 237
- Men of Science in the Modern State (Lord Winster), 231
- Mental Disorder · Biochemistry of (Psychiatry Section of the Royal Society of Medicine meeting on), 101
- Mental Maturity : The Concept of (Prof A. W. Wolters), 494
- Mepacrine on Diamine Oxidase : Action of (Dr. H. Blaschko and Ruth Duthie), 113
- Mepacrine in Human Urines : Primary Degradation Products of (D. Ll. Hammick and S. F Mason), 718
- Mepacrines (Optically Isomeric) : Properties of (Prof. G. F. Gause), 784
- Hg—C Bond . Energy of the, and the Heat of Atomization of Carbon (Prof. N. V. Sidgwick and H. D. Springall), 599
- $HgCl_2$ Vapour : Thermal Decomposition of (Dr. K. Wieland), 504
- Meredith's Actinomycetes : Inhibition of the Development of *Fusarium oxysporum cubense* by a Growth Substance produced by (Dr. A . C. Thaysen and K. R. Butlin), 781
- Merino : The (H. B. Austin), *review* by Dr. J. E. Nichols, 251
- Meson (Neutral) : Life-time of the (Dr. A. Pais), 715
- Mesophyll Cell Walls of the Leaf : Physical Conditions of the Surface o the (Prof. Francis J. Lewis), 407
- Mesotrons at Low Energies : Energy Spectrum of (S. K. Ghosh and N. N. Das Gupta), 83
- Metabolism : Anærobic, of Spermatozoa (Dr. T. Mann), 80
- Metal Antifouling Paints (Heavy) : Anomalous Inactivation of (Prof. John E. Harris), 206
- Metal Industry : X-Ray Methods in the (Society of Czechoslovakian Mathematicians and Physicists conference on), 473, 502
- Metal Single Crystals : Effect of Alpha-Ray Bombardment on Glide in (Prof. E. N. da C. Andrade), 113
- Metal Surfaces : Lubrication of, by Fatty Acids (Dr. F. P. Bowden, J. N. Gregory and Dr. D. Tabor), 97
- Metallic Contact : Closure and Partial Separation of a (Dr. Alan Fairweather), 545
- Metallic Couples : Hydrogen Overvoltage as a Factor in the Corrosion of (L. F. LeBrocq and H. C. Cocks), 536
- Metallic Films (Thin) : Resistivity of (Prof. A. Van Itterbeek and L. De Greve), 634
- Metallography of Magnesium and its Alloys (Walter Bulian and Eberhard Fahrenhorst), translated by the Technical Staffs of F. A. Hughes and Co., Ltd., and Magnesium Elektron, Ltd., *review*, 614
- Metallurgy : National Certificates in, 138
- Metals · The Corrosion of (Institute of Physics, London and Home Counties' Branch, discussion on), 435
- Metals (Liquid) : Electrical Resistance of (Prof. K. S. Krishnan and A. B. Bhatia), 503
- Metaphysical Thinking : The Nature of (Dorothy M. Emmet), *review* by Prof. L. J. Russell, 217
- Meteoric Theory of the Origin of the Earth and Planets (Dr. O. J. Schmidt), 185
- Meteorologists : Climatology for, *review* by Prof. D. Brunt, 157
- Meter and Instrument Jewels and Pivots (G. F. Shotter), 89
- Methodology of the Social Sciences (Prof. Felix Kaufmann), *review* by Prof. David Mitrany, 278
- *Meuschenia skottowei* after a Major Injury : Survival of a specimen of (Elizabeth C. Pope), 714
- Mexico : Earthquake off Mazatlan on April 15, 201
  - (west of) : Earthquake on May 19, 201
- Mice : Mammary Cancer in (Dr. E. Boyland), 787
  - Mammary Tumours in (Members of the Staff of the National Cancer Institute, United States Public Health Service), 787
- Microbiological Assay of Riboflavin (Stanley A. Price), 171
- Microchemistry : The Teaching of Analytical Chemistry in Great Britain, with special reference to (Dr. Cecil L. Wilson), 588

crofilm and other Means of Documentary Reproduction (Association of Special Libraries and Information Bureaux conference on), 24
crographs : Electron Shadow-, of Hæmocyanin Molecules (Prof. Robley C. Williams and Dr. Ralph W. G. Wyckoff), 68
cro-organisms . Growth-Factors and Growth Inhibitors for (Dr. B. C. J. G Knight), 86
  Nature of the Gram-positive Complex in (Dr. H. Henry, Dr. M. Stacey and Dr. Ethel G Teece), 720
croscopy : Fluorescence, of Tubercle Bacilli (Dr. B. Juricic, Sr. Nicolás Vuskovic, Dr. Gastón González, Dr. Hernán Durán and Dr. Hipólito Vergara), 16
crotome Sections : Use of Hydrochloric Acid for Softening Algal Tissues for (Dr. Kathleen M Drew), 479
crowave Radiation from the Sun (G. C. Southworth), 274
ddle East Field Biology, 532
lk : The Secretion of (Prof. H. D. Kay), 159
lk Hygiene, *review*, 406
lk Supply : Bacteria in relation to the (G. H. Chalmers), third edition, *review*, 406
ller (Willet G.) Medal of the Royal Society of Canada awarded to Dr. M. E. Wilson, 271
llport Marine Laboratory : Research Work at the, 668
lne's Theory of Gravitation : The Two-body Problem in (G. J. Whitrow), 365
nd (Infant's) : Measuring the, *review* by Dr. John Cohen, 349
neral and other Resources of East and West Africa : The Contribution of Colonial Geological Survey to the Development of the (Sir Edmund Teale), 167
neral Rights : Nationalization of (Dr. L. Dudley Stamp), 667
nister of Food in Peace-time : If I were (Sir John Boyd Orr), 292
ites : Tyroglyphid, and Human Disease (Dr. G. Lapage), 427
itosis in Animal Cells : Demonstration of (Dr. W. S. Bullough), 574
oisture Meter · An Electrical (Dr. L. Hartshorn and W. Wilson), 16
olecular Giants : X-Ray Adventures among the Proteins and other (Dr. W. T. Astbury), 427
olecular Morphology of Myosin (Dr. W F. H M. Mommaerts), 631
olluscan Family Planorbidæ (Frank Collins Baker), *review* by F. Martin Duncan, 765
olten Salts : Activation Energy of Ionic Migration in (Dr. E. Heymann and H. Bloom), 479
olybdenite Crystals : Effect of Temperature on Magnetic Susceptibility of (Ajit Kumar Dutta), 240
Molybdenum Deficiency in New Zealand · A Case of (Dr. R. B. Davies), 392
Monolayers · Reactions in (Prof. E. K Rideal), 468
Moon : New Map of the (H. Percy Wilkins), 501
Morale in Industry, 91
Morality (International) : The Problems of Education in (United Nations Fellowship discussion on), 444
Morals : Politics and (Benedetto Croce), translated from the Italian by Salvatore J. Castiglione, *review* by Prof. A. D. Ritchie, 281
Morphology : Molecular, of Myosin (Dr. W. F. H. M. Mommaerts), 631
Moths : Some British (Norman Riley), *review*, 34
Motor Response from Giant Fibres in the Earthworm (Dr. W. A. H. Rushton), 109
Moulds : Antibiotics from (J. Kent and N G. Heatley), 295
Mounting Parasitic Helminths · A Medium for (Dr. Fei-pai Li and Fu-hsi Yang), 297 ; (Dr. G. Lapage), 298
Moving-Coil Instruments (G F. Tagg), 396
Moxon Medal of the Royal College of Physicians awarded to Sir Alexander Fleming, 531
Multiple Correlation by means of Stereographic Projection : Estimation of (G. F. K. Naylor), 58
Multiplication *in vitro* of Koch Bodies of *Theileria annulata* (I. Tchernomoretz), 391
Muscle : Crystallization and Identity of the Triose and Triosephosphate Dehydrogenases of (Ranwel Caputto and Dr. Malcolm Dixon), 630
  Structure of Biological Fibres and the Problem of (Dr. W. T. Astbury), 89
  (Ischæmic) : Synthesis of Adenosine Triphosphate by an Enzyme System from (Marian Bielschowsky and Prof H. N. Green), 117
  (Mammalian Striated) : Regeneration of (Prof. W. E. Le Gros Clark), 109
Muscle Fibre Membrane : Cation and Anion Permeability Constants for the (Prof. E. J Conway and P. T. Moore), 170
Muscle Fibres in relation to Carbon Dioxide Tension : Rate of Entrance of Ammonia into (Prof. E. J. Conway and P. T Moore), 270
Muscle Proteins : Heat Coagulation of (Dr. E. C. Bate-Smith and J. R. Bendall), 632
Museums : British, during the War Years, 26
  Natural History, and Research, 277
  New Zealand (Dr. W. R. B. Oliver), 165
Museums in France . Reorganization of, 641
Museums and the Community, 165
Museums and Art Galleries as a National Service, 249
Mutations in Bacterial Virus (S. E. Luria), 304
Mycobacterium tuberculosis : Activity of Helvolic Acid against (M. A. Jennings), 633
Myosin : Molecular Morphology of (Dr. W. F. H. M. Mommaerts), 631
Mysticism ; Science and, *review* by Dr. G. Lapage, 763

NAKURU, Kenya Colony : Report on the Excavations at Hyrax Hill, 1937–1938 (Mary D Leakey), 722
Narcotic Drugs and their Raw Materials · Pre-War Production and Distribution of (L. F. Atzenweiler), 361
National Certificates in Metallurgy, 138
National Defence : Science and, 29, 63, 457
National Geological Reserves in England and Wales (Report by the Geological Sub-Committee of the Nature Reserves Investigation Committee), 485
National Parks in the United States, 15
National Physical Laboratory for India, 15
National Service : Museums and Art Galleries as a, 249
Nationalization of Mineral Rights (Dr. L. Dudley Stamp), 667
Natural Colouring Matters : The Chemistry of (Dr. Fritz Mayer), translated and revised by Dr. A. H. Cook, *review* by Prof. W. Baker, 552
Natural History Museums and Research, 277
Natural Principles of Land Use (Edward H. Graham), *review* by Sir John Russell, 675
Natural and Social Sciences : The Inter-relations between the (Association of Scientific Workers discussion on), 652
Naturalist of the Highlands, *review* by Dr. F. Fraser Darling, 219
Nature for Service Men : Copies of (Lieut.-Colonel J P. Castle), 140
Nature, Nurture and Probability (Prof Gunnar Dahlberg), 539
Naval Research and Development, 472
Navigation : Astronomical Air (Squadron-Leader Ronald Hadingham), second edition, *review*, 489
Navigational Aid : A Radio, 542
Nazi Psychology : The Inferiority Complex and the Paranoid Tendency, with a Brief Reference to (Dr. William Brown), 259
Nemertine : A British Freshwater (Rachel R. Braithwaite and Evelyn B. Clayton), 237
Neomys fodiens : Mass Movement of the Water Shrew (Frances Pitt), 247
Nerve Centres in Biology and Medicine : Direct Chemical Action upon (Prof. Lena Stern), 7
Nerve Fibres : Structure, Degeneration and Repair of (J Z. Young), 132
Neuromuscular Transmission (Synaptic and) : An Electrical Hypothesis of (Prof. J. C. Eccles), 680
Neurospora : Heterokaryosis and the Mating-Type Factors in (Eva Sansome), 47
Neutral Meson : Life-time of the (Dr. A. Pais), 715
Neutron-Proton Scattering at 8·8 and 13 MeV. (Mario Bunge), 301
New Jersey : Description of a New Genus and Species of Apogonid Fish from (Henry B. Fowler), 395
New Zealand : Earthquakes registered during January, 79 ; during February and March, 264 ; during April, 544
  (east of) : Earthquake on April 19, 201
  Earthquakes in, during 1942 and 1943 (R. C Hayes), 396
  Indigenous Forests of (Prof. E. P. Stebbing), 60
  Geography in, 44
  A Case of Molybdenum Deficiency in (Dr. E. B. Davies), 392
  Soil Erosion in (Kenneth B. Cumberland), *review* by G. V. Jacks, 703
New Zealand Geographer, No. 1, 44
New Zealand Museums (Dr. W R. B Oliver), 165
New Zealand State Forest Service : Report for 1944, 60
Newfoundland Area including Labrador : A Biological and Economic Study of the Cod (*Gadus callarias* L.) in the (Dr. Harold Thompson), 213
Newton, Isaac : A Hitherto Unpublished Letter of, 193
Nickel in Eruptive Rocks : Distribution of Vanadium, Chromium, Cobalt and (Prof. L. R. Wager and R. L. Mitchell), 207
Nietzsche and Science (Mario Bunge), 263
Nigeria, its Geology and Mineral Resources (Dr. F. Dixey), 362
Nitration ? (Aromatic) : Univalent Electron Transfers in (G. A. Benford, C. A. Bunton, E. S. Halberstadt, Dr. E D. Hughes, Prof. C. K. Ingold, G. J. Minkoff and R. I. Reed), 688
Nitrogen (Active) : Radioactivity of (Dr. Kai Siegbahn and Dr. Hilding Slätis), 568
Nitrous Nitrogen from Soils on Desiccation : Losses of (Dr. M. R. Madhok and Fazal-Uddin), 49
Nobel Prize
  for Chemistry for 1944 awarded to Prof. Otto Hahn, 657
  for Chemistry for 1945 awarded to Prof. Artturi Virtanen, 714
  for Medicine for 1945 awarded jointly to Sir Alexander Fleming, Sir Howard Florey and Dr. E B. Chain, 533, 564
  for Physics for 1945 awarded to Prof. Wolfgang Pauli, 657
Nodule Bacteria (Legume) : Effective and Ineffective Strains of (Dr. H. G. Thornton), 654
Nomenclature of Animal Behaviour : Classification and (Dr. J. S. Kennedy), 754
Non-Metallic Deposits of the U.S.S.R. (S. I. Tomkeieff), 759
Non-Piezo-Electric Crystal Plates · Shear Modes in (Prof. S. Bhagavantam and J. Bhimasenachar), 23
Nova Tamm, 473
Nubian Sandstone : Geology of the (Dr. N. M. Shukri), 116
Nuclear Energy Generation in the Sun (N. R. Sen and U R. Burman), 305
Nuclear Excitation by means of X-Rays : An Attempt to obtain (Sigvard Eklund), 690
Nuclear Substances · Differentiation of (Ch. Wunderly), 750
Nucleic Acid (Solid) : Adsorption of Enzymes on (Dr. J. A. V. Butler), 781
Nucleons (Fast) : Penetration of, into Heavy Atomic Nuclei (Prof. L. Rosenfeld), 141
Number and the Atom : Time, (R. Fortescue Pickard), *review* by F. J. Garrick, 489
Nurture and Probability : Nature, (Prof. Gunnar Dahlberg), 539
Nutrition : Some British Work on (Dr. G. Lapage), 123
  The Science of (Prof. Henry C. Sherman), *review*, 318
  (Human) · Fermentation and (Dr. B. S. Platt), 87
Nutrition in Jamaica, 288
Nutritive Value of Coco-nut (Dr. J. M. Vandenbelt), 174
Nutritive Values of War-time Foods (Medical Research Council War Memorandum No 14), 330

OBSTACLES : Avoidance of, by Bats (Prof. H. Hartridge), 55
Oceanic Phytoplankton : Autotropic Flagellates as the Major Constituent of the (Dr W. R. G. Atkins), 446
Oceanographical Results of the Last Voyage of the U.S. Non-Magnetic Ship *Carnegie* (Dr. G. E. R. Deacon), 341
Oceanography : Swedish, during the War (Prof. Hans Pettersson), 180
  (Physical) : Observations and Results in (H. U. Sverdrup, F. M. Soule, J. A. Fleming and C. C. Ennis), 341
Œdema in Hamsters Infected with *Leishmania* (L. G. Goodwin), 476

Oils : Utilization of Carotene from (S. Dattatreya Rao), 234
  Influence of Vitamin E on the Utilization of Carotene from (S. Dattatreya Rao), 449
  (Different) : Comparative Vacua produced by, in a Diffusion Pump (Kamalesh Ray and Nanda Dulal Sengupta), 636
Onandaga Salt Works of the New York State, 1646–1846 (Greville Bathe), 758
Onion Eelworm : Calomel and (Dr T. Goodey), 393
Onychophora . South African (Dr. S. M. Manton), 338
Operation of the Fast Geiger-Muller Counter : Effect of the Pressure of Alcohol Vapour on the (Dr. G. D. Rochester and C. B. A. McCusker), 366
Operational Calculus Made Easy : Heaviside's (Dr. T. H. Turney), *review* by Dr. L. E. C. Hughes, 6
Operational Control of Electricity Supply Systems (W Kidd and E. M. S. McWhirter), 361
Operators in Quantum Theory (J L. B. Cooper), 54
Optical Equipment (Precision Engineering and) : Coventry Gauge and Tool Co , Ltd., Taylor, Taylor and Hobson, Ltd., and E. R. Watts and Son, Ltd., to co-operate in the development and distribution of, 387
Optically Isomeric Mepacrines · Properties of (Prof. G. F. Gause), 784
Organ Extracts · An Undialyzable Pressor Principle in (Prof. U. S. v. Euler and E Ostlund), 49
Organic Activities · The Directiveness of (Dr. E. S. Russell), *review* by Dr C H. Waddington, 731
Organic Colouring Matters Natural, *review* by Prof. W. Baker, 552
Organisms (Marine) · Chemical Composition of (S. I. Tomkeieff), 607
Oriental Culture : Indology and (Royal Asiatic Society of Bengal conference on), 687
Origin of the Earth and Planets : A Meteoric Theory of the (Dr. O J. Schmidt), 185
Origin of Uniformity, *review* by Dr. John Cohen, 515
Origin of the Solar System · New Views of the (Prof. W. H. McCrea), 466
Osler Medal for 1945 awarded to Dr. C. G. Douglas, 17
Ottawa : Agricultural Adviser at (Appointment of A. N. Duckham as), 138
Ourselves Unborn (George W. Corner), *review* by Dr. C. H. Waddington, 375
Output and the Worker (P E P Broadsheet), 91
Ovarioles of the Desert Locust (Eggs and) · Presence of Reddish Pigment in, and its Probable Phase Significance (Dr. M L. Roonwal), 19
Over-Current Relays on Medium-Voltage Circuits (A. G. Shreeve and P. J. Shipton), 305
Oxidation : Periodate, of Sugars in Neutral Phosphate Buffer (Gosta Lindstedt), 448
Oxidation and Reduction in Chemistry (Prof J Kenner), 369
Oxygen (Earth's Atmospheric) : Stability of the (Alfred Lauck Pearson), 504
Oyster-Culture in the Thames Estuary . Utilization of the Slipper-Limpet (*Crepidula fornicata*) as Food as an Aid to the Recovery of (Prof. J. H. Orton), 665

PACIFIC (Central) : Callianassidæ of the (Charles Howard Edmondson), 395
Pacific Tunas : A Systematic Study of the (H. C. Godsil and Robert D. Byers), 184
Pacific Waters : 'Palolo' Worms in (R. A. Lever), 19
Packing of Regular (Spherical) and Irregular Particles (R. L. Brown and P. G. W. Hawksley), 421 ; (H S. Leftwich), 753
Paederia foetida Linn · An Endodermal Phellogen in the Stem of (Dr. P. Maheshwari), 116
Paget (Stephen) Memorial Lecture of the Research Defence Society (Sir William Savage), 417
Paints (Heavy Metal Antifouling) : Anomalous Inactivation of (Prof. John E Harris), 206
Palæobotany : Geology and, in the U.S.S R. (W. N Edwards), 282
Palæontology : Vertebrate, in the U S.S.R. (Prof. D. M. S. Watson), 225
Palestine . Plant Pathology in, 713
Palolo Worms (Prof. Hubert Lyman Clark), 508
'Palolo' Worms in Pacific Waters (R A. Lever), 19
Paludrine, a New Anti-malarial Drug, 596
Panama · Earthquake in Chiriqui Province on June 3, 545
Paper Capacitors · Chemically Stabilized (D. A. McLean), 455
Paranoid Tendency · The Inferiority Complex and the, with a Brief Reference to Nazi Psychology (Dr. William Brown), 259
Parasites (Blood-sucking) : Hæmoglobin in (Prof. H. Munro Fox), 475

Science and Ethics (Prof John A. Ryle), 619, 623
Science of Explosives (Prof. Martin Meyer), *review* by Prof. John Read, 5
Science and Foreign Policy (G. Fielding Elliot), 63
Science and the Idea of God (William Ernest Hocking), *review*, 281
Science and International Scientific Co-operation in Post-War World Organisation : The Place of (Dr. Joseph Needham), 558
Science in Kweichow and Kuangsi (Dr. Joseph Needham), 496
Science and Mysticism, *review* by Dr. G Lapage, 763
Science and National Defence, 29, 63, 457
Science of Nutrition (Prof. Henry C. Sherman), *review*, 318
Science of Philosophy : The Foundation of Phenomenology—Edmund Husserl and the Quest for a Rigorous (Prof. Marvin Farber), *review* by F. Ian G. Rawlins, 516
Science and Pig-keeping, *review* by Dr. John Hammond, 434
Science and the Planned State (John R. Baker), *review*, 614
Science in Primary Schools : The Place of (H. Benfield), 56
Science and Reconstruction (Sir John Anderson), 711, 733
Science and Religion (Prof. H. Dingle), 232
Science in Secondary Schools : The Teaching of (E. J. Rose), 56
Science and the United Nations (Dr. Julian Huxley), 553
Science in the United Nations Organisation, 625
Science and the University (Prof. S Brodetsky), 57
Science in the U S.S R :—Physiology (Prof. E D Adrian), 222 ; Contemporary Physics (Prof. E. N. da C Andrade), 223 ; Archæology and Anthropology (Prof. V. Gordon Childe), 224 ; Vertebrate Palæontology (Prof. D. M. S. Watson), 225 ; Medicine (Prof. Arnold Sorsby), 226 ; Agrochemistry (Dr. E. M. Crowther), 227 ; Evolutionary Biology and related Subjects (Dr. Julian Huxley), 254, *errata*, 293 ; Crystallography (Dr. W. A Wooster), 256 , Pedology (Dr. Alex Muir), 258 ; Geology and Palæobotany (W. N. Edwards), 282 ; Physical Chemistry (Prof. C. N. Hinshelwood), 283 ; Surface Chemistry (Prof. N. K. Adam), 284 , Astronomy and Terrestrial Magnetism (Sir Harold Spencer Jones), 324 ; Theoretical Physics (Prof. M. Born), 325
Science and War, 659
Science at War : Radar—a Report of, 444
Science (Engineering and) . Research Fellowships in, 659
Science Film in Education (Miss Dorothy Grayson), 426
Science Magazine . A new series of programmes by the B B.C., 140
Sciences (Natural and Social) : The Inter-relations between the (Association of Scientific Workers discussion on), 652
Sciences (Social) : Methodology of the (Prof. Felix Kaufmann), *review* by Prof David Mitrany, 278
Scientific Affairs in Europe, 576
Scientific Civil Service, 643
Scientific Commission . A Permanent International (Prof. J. D. Bernal), 557
Scientific Co-operation with Czechoslovakia, 416
Scientific Co-operation in Post-War World Organisation (International) : The Place of Science and (Dr. Joseph Needham), 558
Scientific Film . Teaching by means of the (J. Maddison), 57
Scientific Film Needs in Technical Training (W. F. Andrews), 426
Scientific Freedom : Atomic Energy and, 564
Scientific Instrument Industry : Man-Power and Training in the, 154
Scientific Intercourse . Freedom of, 215
Scientific Man-power and Resources : Committee on, 686
Scientific Rehabilitation in Europe, 472
Scientific Research : Film as an Instrument of (Derek Stewart), 426
  Freedom for (Lord Brabazon of Tara), 746
Scientific Research in Canada : Post-War Planning for (Dr. C. J. McKenzie), 500
Scientific Research in India : Fellowships for, 107
Scientific Research in India and the British Colonies, 758
Scientific Service in Britain : A State, 643
Scientific Theory of Culture, and other Essays (Bronislaw Malinowski), *review* by Dr. C. S. Myers, 218
Scientist and the Economic and Social Council (Guy B. Gresford), 625

——cientists : Lessons of the War for (Prof. J. D. Bernal), 659
(Government) : A New Deal for, 644
ea-Level in Glacial Times : Lowering of (A. Farrington), 396
ecretion of Milk (Prof. H. D. Kay), 159
eeds (Bearded Iris) : Germination of (L. F. Randolph and L. G. Cox), 395
eismology (Perry Byerly), *review* by E. Tillotson, 95
ensation : Cause and, in Philosophy, *review* by Prof. A. D. Ritchie, 33
ense Organs (Human) : Conditioned Excitors and (Prof. Krikor Kekcheyev), 573
eparation (Partial) : Closure and, of a Metallic Contact (Dr. Alan Fairweather), 545
Sera : Anti-*Hr* (Dr. Philip Levine), 418
Serological Reactions : The Specificity of (Dr. Karl Landsteiner), revised edition, *review* by Capt. J. A. R. Miles, 348
Serum (Human) : Enhancement of the Action of Immune Hæm-Agglutinins by (K. E. Boorman, B. E. Dodd and Dr. W. T. J. Morgan), 663
Serum Albumin (Human) : Heterogeneity of (H. Hoch and C. J. O. R. Morris), 234
Serum Proteins in the Ultracentrifuge (J. St. L. Philpot), 247
Serum and Serum Fractions : Ultracentrifugal Studies on (Dr. Kai O. Pedersen), 247
Service Men : Copies of *Nature* for (Lieut.-Colonel J. P. Castle), 140
Sewage Filters (Percolating) : Control by D.D.T. of Flies Breeding in (T. G. Tomlinson), 478
Sex Education—Aims, Possibilities and Plans (Cyril Bibby), 412, 438
Sexual Differentiation of the Gonad and the Sexualization of the Germ Cells in Teleosts (Prof. Umberto D'Ancona), 603
Sexual Reproduction Cycle of *Trypanosoma congolense* Broden (R. N. T.-W.-Fiennes), 390
Sexualization of the Germ Cells in Teleosts : Sexual Differentiation of the Gonad and the (Prof. Umberto D'Ancona), 603
Shadow-Micrographs : Electron, of Hæmocyanin Molecules (Prof. Robley C. Williams and Dr. Ralph W. G. Wyckoff), 68
Shear : Viscosity of Ordinary Liquids at High Rates of (L. Grunberg and Dr. A. H. Nissan), 241
Shear Modes in Non-Piezo-Electric Crystal Plates (Prof. S. Bhagavantam and J. Bhimasenachar), 23
Sheep (J. F. H. Thomas), *review* by Dr. J. E. Nichols, 251
Shirley Fellowship Awards, 200, 686
Shrubs as Food for Cattle : Use of Trees and, 151
Sight without Glasses (Good) : The Bates Method for (Dr. William H. Bates), *review*, 281
Silicic Acid Jellies for Bacteriological Purposes : Preparation of (Bjorn Ingelman and Ingvar Jullander), 572
Size : An Illusion of (Prof. H. Hartridge), 118, 636 ; (J. Phelps), 269 ; (Robert Weil), 636
Skin Burns by Hot Gases : Production of (O. M. Lidwell), 298
Sky : The Night, in August, 108 ; in September, 232 ; in October, 387 ; in November, 502 ; in December, 660 ; in January, 777
(Night) : Infra-Red Spectrum of the (R. Herman, L. Herman and J. Gauzit), 114
Slide-Culture Technique : A Modification of (P. H. B. Talbot), 391
Slipper-Limpet (*Crepidula fornicata*) as Food as an Aid to the Recovery of Oyster-Culture in the Thames Estuary : Utilization of the (Prof. J. H. Orton), 665
Smith (J Lawrence) Medal of the United States National Academy of Sciences for 1945 awarded to Stuart H. Perry, 575
Smith (Theobald) Gold Medal of the American Academy of Tropical Medicine awarded to Dr. C. M. Wenyon, 473
Smithsonian Publications Available for Distribution : Classified List of (Helen Munroe), 362
Soap : Efficacy of D.D.T. in (G. A. Campbell, F. C. Hymas and Dr T. F. West), 749
Social Learning and Imitation (Neal E. Miller and John Dollard), *review* by Dr. John Cohen, 515
Social Psychiatry, *review* by Dr. J. Leycester King, 279
Social Sciences : Methodology of the (Prof. Felix Kaufmann), *review* by Prof. David Mitrany, 278
Social Security for Chemists (British Association for Chemists, London Section, open meeting on), 331
Social Studies : Method in, *review* by Prof. David Mitrany, 278
Social and Economic Fields : International Co-operation in, 231
Sodium Doublet Lines : Splitting of the (Prof. N. R. Tawde, B. S. Patil and G. K. Mehta), 662
Sodium Fluoride : Formation of an Addition Compound of Calcium Silicate and (Cyrill Brosset), 451
Soil (Very Acid) : Accumulation of Sugars in Barley Seedlings on (T. W. Barnes), 692
Soil Erosion in New Zealand (Kenneth B. Cumberland), *review* by G. V. Jacks, 703
Soils : Losses of Nitrous Nitrogen from, on Desiccation (Dr. M. R. Madhok and Fazal-Uddin), 49
Soils of Equatorial Regions with special reference to the Netherlands East Indies (Prof. Dr. E. C. Jul. Mohr), translated from the Nederlandsch by Robert L. Pendleton, *review* by Dr. A. Muir, 93
Soils (Acid) : Determination of Factors Injurious to Plants in (Prof. T. Wallace, E. J. Hewitt and D. J. D. Nicholas), 778
Solar Activity : A Forecast of (Dr. W. Gleissberg), 539
Solar Corona : A Physical Theory of the (Dr. A. Hunter), 649
Solar Cycle : Behaviour of Ultra-Violet and Daylight Rays in the (Dr. J. R. Ashworth), 115
Solar Energy : Plant Life and, *review* by Prof. F. J. Lewis, 487
Solar Radiation : Departure of Long-Wave, from Black-Body Intensity (Sir Edward Appleton); 534
Solar System : A New Cosmogony of the (Dr. A. Hunter), 378
New Views of the Origin of the (Prof. W. H. McCrea), 466
Solid Substances : Spectral Analysis of (Dr. J. Eeckhout), 175
Solids (Extended) : Measurement of Ultrasonic Velocities in (R. Parshad), 637
Solutes (Two) : Chromatography of (Dr. E. Glückauf), 205, 571 ; (A. C. Offord and Dr. J. Weiss), 570
Solution of Alkali Halides in Borax and B_2O_3 Glass Systems : X-Ray Study of the (S. K. Majumdar, B. K. Banerjee and K. Banerjee), 423
Solutions : Time Dependence of Interfacial Tension and Density in (Prof. George Antonoff), 301
Solutions of Salts of Penicillin : Concentration of (Dr. S. W. Challinor and Mrs. Jean MacNaughtan), 602
Solvent for Melanin : A Neutral (A. J. Lea), 478
Space-Group of Co_2-Al_9 : Unit Cell and (Audrey M. B. Parker), 783
Spain : Earthquakes registered during January, 79 ; during February, 79 ; during March, 264 ; during April, 544
Special Librarian in Industry : Some Problems of the (E. N. Simon), 605, 606
Specificity of Serological Reactions (Dr. Karl Landsteiner), revised edition, *review* by Capt. J. A. R. Miles, 348
Spectra of Coals : Infra-Red (C. G. Cannon and Dr. G. B. B. M. Sutherland), 240
Spectra of Diatomic Oxides by the Method of Exploded Wire (B. Rosen), 570
Spectral Analysis of Solid Substances (Dr. J. Eeckhout), 175
Spectral Structure of the Inert Gases (Prof. Bengt Edlén), 445
Spectroscopy : Infra-red (R. Bowling Barnes, Robert C. Gore, Urner Liddel and Van Zandt Williams), *review* by Dr. H. W. Thompson, 65
Spectrum : Energy, of Mesotrons at Low Energies (S. K. Ghosh and N. N. Das Gupta), 83
Infra-Red, of the Night Sky (R. Herman, L. Herman and J. Gauzit), 114
Spectrum of Iodine : Emission Bands of the Fluctuation Type in the (Prof. R. K. Asundi and P. Venkateswarlu), 452
Speech : Is Human, Good Enough ? (Sir Richard Paget), 209
Spermatozoa : Anærobic Metabolism of (Dr. T. Mann), 80
Spermatozoa in Egg-Yolk Medium : Respiration of (J. Tošić and Dr. Arthur Walton), 507
Spherical Harmonics : The Theory of Potential and (Wolfgang J. Sternberg and Prof. Turner L. Smith), *review* by J. H. Pearce, 5
Spicules on the Sun (Dr. Walter O. Roberts), 362
Spider : The Black Widow, *review* by T. H. Savory, 253
Splitting of the Sodium Doublet Lines (Prof. N. R. Tawde, B. S. Patil and G. K. Mehta), 662
Spraying : Control of Weeds by, 330
Squat : The Popliteal Facet in Men who Habitually (Prof. M. A. Shah), 237
Squirrels (Grey) : Inheritance of Melanism in (Monica Shorten), 46
Stability of the Earth's Atmospheric Oxygen (Alfred Lauck Parson), 504
Stabilization of Penicillin Solutions by Phosphate (Lieut.-Colonel R. J. V. Pulvertaft and Capt. John Yudkin), 82
Staphylococcus aureus Infections : Effect of Tissue Extracts in controlling (Dr. Leo G. Nutini and Sr. Eva Maria Lynch), 419
Starch in Cultures of Capsulated Yeasts (Extracellular) : Production of (Dr. M. Aschner, J. Mager and Dr. J. Leibowitz), 295
Starch Storage in the Barley Grain : Some Factors concerned in the Process of (H. K. Archbold), 70
Stars for Eros (Southern Comparison) : Re-Observation of the Magnitudes of the (R. H. Stoy and A. Menzies), 179
State (Modern) : Men of Science in the (Lord Winster), 231
Statistics in the (Lord Woolton), 686
State (Planned) : Science and the (John R. Baker), *review*, 614
State Scientific Service in Britain, 643
Statesman's Year Book for 1945 (edited by Dr. M. Epstein), *review*, 614
Static : Cosmic (Grote Reber), 396
Statistical Methods : Application of, to Mechanical Test Results (Dr. B. Chalmers and E. R. W. Jones), 307
Statistical Problems : Use of Stereographic Projection for (Prof. Cyril Burt), 338
Statistics in the Modern State (Lord Woolton), 686
Steam Tables : The 1939 Callendar (G. S. Callendar and Sir Alfred Egerton), second edition, *review* by Dr. H. Heywood, 462
Steam Tables and Steam Power (Prof. D. M. Newitt and N. R. Kuloor), 755
Steel-Cored Aluminium Conductors : Tensile Load on (E. W. W. Double), 305
Stereographic Projection : Estimation of Multiple Correlation by means of (G. F. K. Naylor), 58
Stereographic Projection for Statistical Problems : Use of (Prof. Cyril Burt), 338
Sterilization of Syringes, 745
Stilbœstrol Solutions (Dienœstrol and) : Instability of (A. E. Wilder Smith and P. C. Williams), 718
Stone Age in East Africa (M. C. Burkitt), 371
Stratosphere Aircraft : New, 44
Strength of Materials (British Rheologists' Club conference on), 306
Stress Cycles (Repeated) : The Behaviour of Natural Rubber and GR-S under (Dr. D. Parkinson and J. L. Bloxham), 11
Stressing : Strength of Glass and Duration of (F. W. Preston), 55
Striated Structure of Age-hardened Alloys (Dr. M. L. V. Gayler), 333
Structural Diagnosis by Infra-red Absorption : Chemical Analysis and, *review* by Dr. H. W. Thompson, 65
Structural Problems in the Polysaccharides : Application of New Methods of End-Group Determination to (F. Brown, Sonia Dunstan, T. G. Halsall, Prof. E. L. Hirst and J. K. N. Jones), 785
Structure, Degeneration and Repair of Nerve Fibres (J. Z. Young), 132
Sub-crystalline Regions in 'Hybrid' Crystals of Potassium Dihydrogen Phosphate : Laue Photographs of (Dr. A. R. Ubbelohde and Miss I. Woodward), 20
Substances (Solid) : Spectral Analysis of (Dr. J. Eeckhout), 175
Sugar Consumption of *Bact. coli* : Effect of Sulphanilamide on the (N. Klissiunis), 178
Sugar-Beet in Dry Climates : Chalk-washing of (Kolossov), 304
Sugar Beet Production : Mechanization of, 361
Sugars in Barley Seedlings on Very Acid Soil : Accumulation of (T. W. Barnes), 692
Sugars in Neutral Phosphate Buffer : Periodate Oxidation of (Gosta Lindstedt), 448
Sulphanilamide : Effect of, on the Sugar Consumption of *Bact. coli* (N. Klissiunis), 178
Sulphur Oxides : Influence of, on the Luminosity of Coal Gas Flames (Dr. G. Whittingham), 207
Sun : Microwave Radiation from the (G. C. Southworth), 274
Nuclear Energy Generation in the (N. R. Sen and U. R. Burman), 305
Radio Waves from the, 273
Spicules on the (Dr. Walter O. Roberts), 362
Sun Compass (Francis Chichester), *review*, 318
Sunset : The 'Green Flash' at, with a Near Horizon (D. R. Barber), 146 ; (Dr. C. E. P. Brooks), 368
Supernova in Canes (M. L. Humason), 777

Suprarenal Cortex . Thiourea and the (Dr Gertrude E Glock), 508
Surface Tension Measurement : Time Factor in (Dr. C. C Addison), 600
Surge Characteristics of a Three-Phase Transmission Line with Earth Wire (W. G Hawley), 305
Survival of a Fish after a Major Injury, 714
Suspensions : General Rheological Properties of (British Rheologists' Club and the Manchester Section of the Oil and Colour Chemists' Association discussion on), 745
Sweden's Water-Power Resources, 759
Swedish Oceanography during the War (Prof. Hans Pettersson), 180
Symbols Used to Indicate Hydrogen Ion Concentration and Similar Quantities (Dr. D. Clibbens), 176
Sympathomometic Pressor Substance in Animal Organ Extracts (Prof. U. S v. Euler), 18
Synaptic and Neuromuscular Transmission : An Electrical Hypothesis of (Prof. J. C. Eccles), 680
Synthesis of Adenosine Triphosphate by an Enzyme System from Ischæmic Muscle (Marian Bielschowsky and Prof H. N. Green), 117
Synthesis of Chondrosamine : A Constitutional (Dr. Sybil P. James, Dr. F. Smith, Dr. M. Stacey and Dr. L. F. Wiggins), 308
Synthetic Rubber from Alcohol (Anselm Talalay and Michael Magat), *review* by Dr. W. J. S. Naunton, 251
Syphilis : Penicillin in the Treatment of (Major James Marshall), 769
Syria . Plant Studies in (Prof. Zohary), 246
Syringes : Sterilization of, 745

TARTAR Deposition in the Ferret . Enamel Cuticle (Nasmyth's Membrane) and (Dr J D King), 572
Tea Chests The Testing of Indian Plywood for (V. D. Limaye), 668
Teaching by means of the Scientific Film (J. Maddison), 57
Team Work in Science, 581
Technical Training : The Film Strip in (H Richmond), 426
  Scientific Film Needs in (W. F. Andrews), 426
Technological Education . Higher, in Britain, 699
Technologist · The Education of the (Prof. J. B. Speakman), 57
Technology and Administration, 671
Technology of Food and Food Products · The Chemistry and (edited by Dr. Morris B. Jacobs), Vol. 2, *review* by Dr. T. Moran, 220
Teeth of Rachitic Rats (Incisor) : Effect of Restriction of Food Intake upon the (Prof J. T. Irving), 664
Teleosts Sexual Differentiation of the Gonad and the Sexualization of the Germ Cells in (Prof. Umberto D'Ancona), 603
Telepathy : A Theory of (A T. Oram), 303
Television System . New (Pye, Ltd.), 565
Temperature : Mass Departure of Locust Swarms in relation to (Dr. D. L. Gunn, Flying-Officer F. C. Perry, Flight-Lieut. W G. Seymour, Flight-Lieut. T M. Telford, A.C 2 E. N. Wright and D Yeo), 628
  Effect of, on Magnetic Susceptibility of Molybdenite Crystals (Ajit Kumar Dutta), 240
Temperature Effect on Ultra-sonic Velocity in Water (Bawa Kanwal Singh), 569
Tensile Load on Steel-Cored Aluminium Conductors (E. W. W Double), 305
Tension and Density in Solutions (Interfacial) : Time Dependence of (Prof. George Antonoff), 301
Termination Coefficients Propagation and, for Vinyl Acetate Photopolymerization (G. M. Burnett and Prof. H. W. Melville), 661
Tetrabromide of β-Phellandrene (P. A. Berry and Prof. A Killen Macbeth), 175
Terrestrial Magnetism and Atmospheric Electricity . Completion of the fiftieth year of publication, 472
Terrestrial Magnetism : Astronomy and, in the U S.S.R. (Sir Harold Spencer Jones), 324
Tetrahydroacridones and related Substances · Antimalarial Activity in (Joan M L. Stephen, Isabel M. Tonkin and James Walker), 629
Thames Estuary : Utilization of the Slipper-Limpet (*Crepidula fornicata*) as Food as an Aid to the Recovery of Oyster-Culture in the (Prof J H. Orton), 665
Thatch Grass (Dr. B C. Sharman), 342
Theileria annulata · Multiplication *in vitro* of Koch Bodies of (I. Tchernomoretz), 391
Theory of Gravitation (Milne's) : The Two-body Problem in (G. J. Whitrow), 365
Thermal Decomposition of $HgCl_2$ Vapour (Dr. K Wieland), 504
Thermal Diffusion in Gases · Effect of Pressure on (K. E. Grew), 267
Thermal History of the Earth (Dr. E. C. Bullard), 35
Thermomechanical Effects in Water . Flow of Water through Very Narrow Channels and Attempts to Measure (Dr. J. Reekie and J Aird), 367
Thermostabile, Fungistatic Factor from *Escherichia coli* (Sten Wiedling), 204
Thinking (Metaphysical) : The Nature of (Dorothy M. Emmet), *review* by Prof. L. J. Russell, 217
Thiourea and the Suprarenal Cortex (Dr Gertrude E Glock), 508
Thompson (Mary Clark) Medal of the United States National Academy of Sciences awarded to Thomas Wayland Vaughan, 575
Thought The Art of Medicine in relation to the Progress of (A. E Clark-Kennedy), *review* by Dr. G. Lapage, 488
Tick . An Arsenic-Resistant (Prof. J. Omer-Cooper and A. B M. Whitnall), 450
Tilden Lecture of the Chemical Society (Prof. E. D Hughes), 777
Timber : Protection of, against Powderpost Beetles, 16
Timber Resources of Britain, *review* by Major T. H. Hawkins, 613
Time Corrections by Equal Altitudes (Zinger's Method) for 1944 : Ephemerides for the Determination of (Astronomical Institute of the Academy of Sciences of the U.S.S.R.), 16
Time Dependence of Interfacial Tension and Density in Solutions (Prof. George Antonoff), 301
Time Factor in Surface Tension Measurement (Dr. C. C. Addison), 600
Time and its Lapse Rate : The Fitzgerald Contraction as the Origin of our Experience of (Prof. W. Peddie), 336
Time, Number and the Atom (R. Fortescue Pickard), *review* by F. J. Garrick, 489
Timor Português, contribuições para a seu estudo antropológico (Pr A. A. Mendes Corrêa), *review* by Prof. A. R Radcliffe-Brown, 1
Tissue Extracts in controlling *Staphylococcus aureus* Infections : Effect (Dr. Leo G. Nutini and Sr. Eva Maria Lynch), 419
Tissues (Animal) . Acetylphosphatase in (B Shapiro and E. Wertheimer 690
Titanates : Dielectric Constants of some (Dr. B. Wul), 480
Toadstools · Trees and (Dr. M. C. Rayner), *review*, 732
Tomato Fruits : Parthenocarpic Production of (Thomas Swarbrick), 300
Tones : Difference (A J. King), 536
  (Difference) : Production of (Prof. Frank Allen), 84
Toothache : Folk-Lore of (Dr. J D Rolleston), 387
Tory (Henry Marshal) Medal of the Royal Society of Canada awarded t Dr. Otto Maass, 271
Toxicity of D D T. to the Housefly (E A Parkin and A. A Green), 745
Toxicity to Fungi in Wareham Heath Soil : Origin of (Dr. M. C. Rayner) 174
Trade (Skilled) : Apprenticeship for a (F. Twyman), 155
Training : Education and, of Aircraft Workers, 78
  Man-Power and, in the Scientific Instrument Industry, 154
Training of Engineers (Prof. Andrew Robertson), 775
Transients (Electrical) : The Simple Calculation of (G. W. Carter), *review* by Dr. L. E. C. Hughes, 6
Transmission (Synaptic and Neuromuscular) : An Electrical Hypothesis o (Prof. J. C. Eccles), 680
Transmission Line (Three-Phase) . Surge Characteristics of a, with Earth Wire (W. G Hawley), 305
Transmission-line Problems : Long (R. H. Paul), 179
Transplantation of the Heart (Prof. Nikolai Sinitsin), 536
Trees : The Wood from the (Richard Jefferies), *review* by Major T. H. Hawkins, 613
  (Apple) : Abnormal Lignification in the Wood of some (Dr A. Bery Beakbane and Dr Eleanor C. Thompson), 145 ; *erratum*, 202
  (Fruit) . Phosphorus Deficiency of (L. R. Bryant and R Gardner), 178
  (Fruit) . Root Distribution of (E L. Proebsting), 395
Trees and Fungi, *review*, 732
Trees and Shrubs as Food for Cattle . Use of, 151
Trees and Toadstools (Dr. M. C. Rayner), *review*, 732
Trichoderma viride . Viridin, a Highly Fungistatic Substance produced by (Dr P. W. Brian and J. C. McGowan), 144
Triose and Triosephosphate Dehydrogenases of Muscle . Crystallization and Identity of the (Ranwel Caputto and Dr. Malcolm Dixon), 630
Tropical Ecological Studies : Need for Development of (Dr. V. J. Chapman, C. O. Flemmich, A. L. Griffith, J. L. Harley, R. Hobbins, C. H. Holmes, C. de Rosayro and J. Wyatt-Smith), 627
Tropical Pedology, *review* by Dr A. Muir, 93
Tropical Plains of Bengal : Artificial Production of Ergot in the (J. C. Saha and S. K. Bhattacharjee), 363
Trypanosoma congolense Broden : A Sexual Reproduction Cycle of (R. N. T.-S.-Fiennes), 390
Tubercle Bacilli : Fatty Constituents of, as Growth-Inhibitors of the same Bacilli (Dr. Ng. Ph. Buu-Hoï), 392
  Fluorescence Microscopy of (Dr. B. Juricic, Sr. Nicolás Vuskovic, Dr. Gastón González, Dr. Hernán Durán and Dr. Hipólito Vergara), 16
Tubercle Bacillus : Production of *p*-Aminobenzoic Acid by the (Torsten Ekstrand and Bertil Sjogren), 476
Tuberculosis : Chemotherapy of (Dr. M. A. Soltys), 210
  Familial Susceptibility to (Dr. Ruth Rice Puffer), *review*, 191
Tumbian Culture in East Africa : A Contribution to the Study of the (Dr. J. B. S Leakey and Archdeacon Owen), 371
Tumour Conditions · Experimental Imitation of (Dr. P. T. Thomas), 738
Tumours . Mammary, in Mice (Members of the Staff of the National Cancer Institute, United States Public Health Service), 787
Tumours Induced in Rabbits by 9 . 10-Dimethyl-1 : 2-Benzanthracene (Histologically Malignant) : Spontaneous Regression of (Stephan Beck), 238
Tunas (Pacific) A Systematic Study of the (H. C. Godsil and Robert D. Byers), 184
Turner and Newall Research Fellowships, 659
Twin Embryos in Angiosperms (Haploid-Diploid) : Origin of (Dr. P. Maheshwari), 173
2 × 2 Tables · A New Test for (G. A. Barnard), 177, 783 ; (Prof. R. A. Fisher), 388
Two-body Problem in Milne's Theory of Gravitation (G. J. Whitrow), 365
Two-Solution Cells . A Convenient 'Bridge' for (Dr. S. M. Neale), 506
Tyndall, John : Life and Work of (A. S. Eve and C. H. Creasey), *review* by Lord Rayleigh, 189
Typhoid, Cholera, Dysentery and *B. coli* . Anti-bacterial Action of 'Polyporin' against (Prof. S. R. Bose), 171
Tyrell Medal of the Royal Society of Canada awarded to Prof F. Landon, 271
Tyroglyphid Mites and Human Disease (Dr. G. Lapage), 427

ULTRACENTRIFUGAL Studies on Serum and Serum Fractions (Dr. Kai O. Pedersen), 247
Ultracentrifuge . Serum Proteins in the (J. St. L. Philpot), 247
Ultrasonic Velocities in Extended Solids : Measurement of (R. Parshad), 637
Ultra-sonic Velocity in Water : Temperature Effect on (Bawa Kanwal Singh), 569
Ultra-Violet Emission Bands : Near, of Benzene (Prof R. K. Asundi and M. R. Padhye), 368 ; (Prof C. K Ingold), 569
Ultra-Violet Light · Porphyrin Fluorescence in the Livers of Pellagrins in relation to (Dr. J. Gillman, Dr T. Gillman and S. Brenner), 689
Ultra-Violet and Daylight Rays in the Solar Cycle : Behaviour of (Dr. J. R. Ashworth), 115

THE UNITED NATIONS

THE San Francisco Conference which issued in the United Nations Charter, signed on June 26, after nine weeks deliberations on the proposals formulated last autumn at Dumbarton Oaks, by the fifty nations represented, has been compared by President Truman with the Philadelphia Convention of 1787 which led to the framing of the Constitution of the United States. Like that Constitution, the United Nations Charter represents a compromise, the outcome of close debate and sometimes sharp exchange of conflicting opinions. Like that Constitution again, the Charter is not claimed to be a final or perfect instrument; and, more clearly than the Covenant of the League of Nations, it provides expressly for its own revision and modification in the light of experience.

Whether the San Francisco Conference will take its place in history with the Philadelphia Convention has yet to be seen. It is only the first step towards a lasting peace—the forging of an instrument, which, whatever the merits or demerits of its content, is truly what the League of Nations never was, a world organization. The signatures on the same Charter of the United States and of Soviet Russia is a greater achievement than any of its 111 articles, and the promptness with which President Truman has sent the Charter to the United States Senate for ratification, and the Russian disposition to stress the responsibilities of the major Powers rather than their privileges, are hopeful signs. Even more hopeful is the sober restraint which has characterized the recognition of this great achievement. There is now far wider recognition that no international instrument, no constitutional specific will suffice to maintain peace; and the absence of extravagant hopes may be one of the firmest assurances that the Charter will command the loyalty and understanding which alone can make it effective.

Regional arrangements are clearly encouraged, the need for peaceful change is duly emphasized, and the clause inserted in Article 1 affirming as one purpose "international co-operation . . . in promoting and encouraging respect for human rights and for fundamental freedoms for all without distinction as to race, sex, language, or religion", does something to meet the call for an international bill of rights inspired by the terrible atrocities of recent years. The biggest step in meeting American criticisms of the Dumbarton Oaks scheme is probably the inclusion of entirely new chapters on trusteeship for non-self-governing territories. These three chapters involve the establishment of an international trusteeship system with a trusteeship council possessing similar functions to those of the League Mandates Commission.

The system thus established holds promise of removing some of the causes of friction and misunderstanding between Great Britain and the United States, as well as between other countries; and these articles, with their emphasis on the encouragement of research and promotion of development, are of special interest to scientific workers. A like observation may be made of the second major addition to the Dumbarton Oaks document—the much fuller elaboration of the scope and functions of the Economic and Social Council. Dismissed rather perfunctorily in Chapter 9 of the Dumbarton Oaks proposals, this scheme has now been developed at length in Chapters 9 and 10 of the new Charter embracing Articles 55–72. The Economic and Social Council, which will consist of eighteen members, is now named as one of the principal organs of the United Nations, and its duties will include that of initiating research and of recommending action to the Assembly on all international economic and social questions, including health.

This is not the place for a detailed examination of the nineteen chapters and 111 articles to which the Charter now runs, but the importance of the document cannot be over-emphasized. It represents first, as already noted, the cardinal and central fact that it is the duty of the powerful nations to assume the responsibility of leadership towards a world of peace, though it should not be forgotten that restraint will also be demanded of the smaller countries in the Economic and Social Council and in the Assembly if dissensions are not to arise. Next, the Charter represents a reasonable attempt to utilize available experience, both of regional bodies and of functional organizations. As President Truman rightly said, it shows that the lessons of military and economic co-operation during the War have been learnt, and that the pooling of experience and resources in the work of the Combined Raw Materials Board, the Food Board and the Combined Chief of Staffs Committee is to be turned to our advantage for the purposes of peace and not rashly jettisoned as in 1919.

But despite the embodiment of such methods and experience in the new Charter, and its close relation to the policies and organization already represented by the United Nations Relief and Rehabilitation Administration, the Food and Agricultural Organization, the monetary Conference at Bretton Woods, and the aviation conference at Chicago, the kernel of the new organization is the Security Council; and, like the League of Nations, the United Nations will ultimately stand or fall by the success or failure of its machinery for the maintenance of peace.

The Charter itself is nothing if it fails to hold the loyalty of the major Powers, who alone can give it body and life. Already it is clear that the leaders of Great Britain, the United States, and the U.S.S.R. are ready to assume the responsibility of leadership towards a world of peace. In addition, we require indeed an effective agency for constant and thorough interchange of thought and ideas, through which alone can come a better and more tolerant understanding among nations and among peoples. An enduring peace involves a victory in the minds of men over the evil ideas and passions that have divided mankind and plunged the world into chaos. It involves the formation of a world opinion which clearly understands the price that has to be paid for peace, the restraints which must be accepted as the alternative to anarchy—the limitations as well as the opportunities of world organization. The creation of that opinion is a matter of education in which there is a place for every man and woman of good will.

R.A.F. AERIAL SURVEY IN PEACE-TIME

THE necessities of war have brought about th development of photographic reconnaissanc upon a scale previously unapproached, and at technical and administrative level of great competence. To achieve this the Royal Air Force ha built upon the pioneer experience of the War c 1914–18, on Services and commercial experienc between the Wars, and on the scientific knowledg of many types of imported specialists in fields relate to aerial survey, such, for example, as archæologists geographers and ecologists.

Now that a stage of hostilities has been reache when peace-time organization deserves attention it is appropriate to recognize that in this branc of R.A.F. activities there exist material an experience of great potential value for those year of post-war development which lie ahead, an during which Great Britain cannot afford to neglec any prospective means of scientific and technica advancement.

These considerations are prompted by a memorandum circulated by the British Ecological Society to scientific authorities and responsible governmen departments, and headed "Memorandum on th Establishment of an Aerial Unit for Scientific Work". Ecology, which has been defined as "scientific natural history", has brought modern techniques of science to bear upon the complex phenomena of plant and animal life in relation to its natural environment. Its workers have constantly concerned themselves with problems of relationships between vegetation, animal life, topography and soil. Their outlook has progressively established itself as fundamental to the disciplines of forestry, agriculture, geography and archæology. It is suitable therefore that ecologists should raise this issue; but it must be apparent that even wider fields than those they mention can be served by the widespread use of aerial mapping.

Photographic aerial survey has immense advantages over ground mapping: apart from the speed with which maps can be constructed from an air survey, air photography records automatically a multitude of distributional features of vegetational, geological, archæological and economic interest, and these remain available for inspection and analysis in the photographic prints. The aerial photographer, even when mapping without specific aim, cannot help but record an infinity of useful facts, of which he remains unaware, but which deliberate ground mapping could either not yield at all or yield only with immense labour. The value of this speedy, accurate and comprehensive mapping is too apparent to need stressing. It immediately affects geography, engineering, economics, and regional and town planning, especially perhaps in areas of great extent, complexity, or inaccessibility. It is, however, to its great potentialities in less obvious directions that our attention is now specially directed.

Archæologists were from the first keenly aware of the potential value to them of the point of view given y the aeroplane, and many new and important sites ave been disclosed by its aid. Thus air photography d to the excavation of Woodhenge in Wiltshire, nd its counterpart at Arminghall in Norfolk, and isclosed the Romano-British system of field boun- aries in relation with the prehistoric river systems f the East Anglian fens. Readers will indeed already e familiar with such achievements through the ublications of Mr. O. G. S. Crawford on the subject, nd through the admirable pioneer investigations of Ving Commander Insall.

Foresters have seized the opportunities of aerial urvey no less readily. Dr. Dudley Stamp in 1925 published results of an aerial survey of Burmese forests in the Irrawaddy Delta ; Dr. Bourne, of the Imperial Forestry Institute, in 1930, indicated its mmense potentialities in regional survey, illustrating his thesis by the aerial survey of tracts of southern England ; Dr. B. Lindquist of Lund was able, by ir survey at a season when the beech foliage con- rasted with that of other trees, to complete a survey of the beech forests throughout southern Sweden ; and more recently foresters in Canada and the United States have mapped and classified immense areas of forest land, and from the air photographs have derived information not only of vegetation types, tree species, and tree density, but also details of composition, age, and structure of the most direct importance to forest management. Other vegetation surveyed from the air includes types so divergent as prairie, sphagnum bog, coastal cliffs and submerged seaweed beds. Very often the changes such types show are intimately associated with topographic processes of great importance, such as those of soil erosion and coastal modification. The study of aerial plankton, the wind's freight of dust, pollen, bacteria, fungus spores and aphids, the rapid detection and report of the movements of big game or of locust swarms, the control of pests by spraying or dusting from the air, are yet other instances which indicate the wide scope of further application of the aeroplane to the service of biological science.

With the proved value of these applications in mind, and supported by an informative schedule of provisional schemes of investigation, the British Ecological Society suggests that after the War there should be established a permanent R.A.F. unit the services of which should be available for scientific work, not necessarily limited to photographic survey though chiefly concerned therein. To the arguments which are offered of the scientific potentialities of air survey thus fostered we would add that the effect upon the service unit of constant contact with men of science of varied kinds, and of attempts jointly with them to solve scientific problems of diverse character, must have the effect of keeping outlook and methods flexible and modern. Moreover, just as in war-time photographic survey has drawn extensively upon the services of academic men of science to help in such problems as the evaluation of cover, penetrability, and similar qualities of unfamiliar vegetation, so it remains desirable from the service point of view to keep and strengthen the links already made with such men of science.

The air photographs already obtained by the R.A.F. are of immense value to Britain, and the memorandum rightly recommends the establishment of a central library of air photographs available for scientific use. There should be destruction of negatives and prints of aerial photographs only where national security clearly demands it : the normal course should be for all good-quality negatives to go to the central library for indexing, and flights for training in air photography could with advantage regularly be made over targets selected for scientific usefulness.

We have mentioned but a fraction of the scientific issues touched by the new proposal, but it is clearly one which must receive warm support from men of science in all parts of the Commonwealth. If suitable administrative machinery can be devised, it should become a tool of great usefulness, helping men of science to maintain in the peace the quality of service they have so conspicuously upheld throughout the War.

GENETICS AND MAJOR EVOLUTIONARY CHANGE

Tempo and Mode in Evolution

By George Gaylord Simpson. (Columbia Biological Series, No. 15.) Pp. xviii+237. (New York : Columbia University Press ; London : Oxford University Press, 1944.) 23*s.* 6*d.* net.

IN "Tempo and Mode in Evolution" G. G. Simpson has done for palæontology what Ernst Mayr, in his "Systematics and the Origin of Species", did for taxonomy—he has reviewed the facts of his special branch of biology in the light of modern genetics. The result is an interesting and significant contribution to the synthesis now occurring in the general field of evolution.

Palæontology had indeed tended to build up its own set of evolutionary concepts, such as orthogenesis, racial senility, evolutionary momentum, and the like, between which and the concepts of neo-mendelism there seemed to be little or no possible connexion. Dr. Simpson has performed the double task of reminding neo-zoologists of many facts of palæontology which they have tended to overlook as unfamiliar or inconvenient, and at the same time showing the possibility of accounting for them in genetic terms.

The most familiar phenomenon brought to light by palæontology is the existence of evolutionary trends, as in the horses, the titanotheres, and almost every group of which there is abundant fossil record. The term orthogenesis has been applied to these sometimes as a description, sometimes as an explanation. Dr. Simpson reminds us that in point of fact these trends, though often broadly directional, are rarely rectilinear for more than short periods, that they may change in rate, that they may be reversed, that they show much branching (the horse stock has at least twelve branches of generic rank, besides the conventionally 'main' line leading to *Equus*). The facts are "flatly inconsistent with the idea of any inherent rectilinearity, predetermined trend, or solely preadaptive control". They can, however, be explained on the basis of orthoselection—selection acting in general in the same direction over long periods.

As a minor additional mechanism, he agrees that certain facts which otherwise demand a mysterious directional urge can be explained as by-products of allometric growth : thus Robb's data indicate clearly that the relative increase of facial length in horses is an automatic by-product of increase in absolute body-size. There are some rather disturbing theoretical consequences of such potentialities being implicit in the original short-faced ancestor; but if we recognize that selection can alter the rate of allometry (a point not clearly brought out by the author) the difficulties are not so great.

At any one period, each main trend or line tends to break up into separate species, adapted to slightly different environments. This Dr. Simpson would explain in essentially the same way as the taxonomist explains the formation of present-day species—by isolation, usually geographical, followed by divergence under the influence of selection. He would, I gather, attach rather more importance to the separating-out, by means of geographical isolation, of different characters, already co-existing in the original population. In support of this point, he adduces some facts (from ammonites) which show that a new line may have unusually low variability at the time of its origin, but that this is later gradually increased to normal. Such studies will be of great importance for evolution theory*.

A fact neglected by most zoologists is that within a general gradual trend, qualitative differentiation may occur, and if so, appears to be (geologically speaking) rapid. Thus the transition from browsing to grazing teeth occurred, in the ancestral true horses, during the Miocene. Dr. Simpson's analysis of this is very interesting. Grazing requires extremely long (hypsodont) teeth, because the food is so abrasive. However, even in browsing types increased size alone means somewhat greater hypsodonty, to meet the greater length of life. For this reason, by the early Miocene, equid teeth were beginning to approach a height suitable for grazing, so that then and only then could selection for grazing begin to act, and suitably isolated populations could evolve rapidly in the grazing direction.

Dr. Simpson then reminds us of the large gaps in the palæontological record, and of the consistency of their occurrence. In spite of the great progress made in tracing continuity of evolution *within* mammalian orders, no fossils have been found bridging the gaps between orders; and this phenomenon is virtually universal. To account for this, he supposes that, for one reason or another, breeding populations in the missing lines were at such periods isolated and small. As Sewall Wright has shown, in such populations evolution may be more rapid than normal, but is also largely non-adaptive. However (and here Dr. Simpson makes a rather new point), such non-adaptive evolution, in relation to existing conditions, may in occasional cases be pre-adaptive in relation to a new mode of life or a new environment; and if so, there will be strong selection-pressure favouring further adaptation along these lines.

If this is correct, we should scarcely ever expect to find transitional forms, as these would be extremely few in numbers and their evolution into the new typ would be unusually rapid.

The only question which will occur to geneticist is whether the very small isolated populations postulated by Sewall Wright as needed for non-adaptiv evolution could persist for the millions of years postulated by Dr. Simpson (for example, p. 121) for hi periods of rapid major change.

When a new favourable area is invaded, a 'explosive' evolution generally occurs, and we ma then find some of the process preserved in fossils. Thus among the South American ungulates in thei earliest phase, "there are so many transitiona forms, some of them quite plainly adaptively unstable, that the taxonomic problem seems almos hopeless".

Dr. Simpson explicitly rejects Goldschmidt's view that large-scale evolution operates by sudden rearrangements of the germinal material to produce new 'reaction systems', and indeed adduces many arguments against it. His main thesis is that there are three main types of evolution—speciation, phyletic or gradual directional change, and the rapid major changes we have just discussed, to which he gives the perhaps not very satisfactory name of 'quantum evolution'. The attention of palæontologists has been chiefly focused on phyletic trends, that of neo-zoologists on speciation : the time has now come for an exchange of views.

There are many other points of interest discussed by Dr. Simpson. One is the question of evolutionary rate. Thus, on palæontological evidence, he is able to conclude that "carnivores have evolved, on an average, at least ten times as fast as pelecypod molluscs". Within a phyletic trend, different branches may show markedly different rates for the evolution of a given character.

It seems clear that the general phyletic evolution of a group may be slow, as seems to be the case for Pelecypods. But there is also the point that phyletic evolution may reach a limit, when specialization has been pushed as far as ortho-selection can take it (most mammalian orders) : after this limit, phyletic evolution will cease and be replaced, in Dr. Simpson's terminology, by speciation (though this may extend to the production of new genera). With this, the rate of evolutionary change will clearly be much slowed down. I think that palæontology should further clarify this question of different types of slow evolutionary rate and the reasons for them. Attention might also have been given to the difference between (one-sided) specialization and (all-round) progress, and its genetic implications.

However, we must not quarrel with a pioneer for not having covered every aspect of the subject. He has introduced us to a new field, where the co-operation of geneticists, taxonomists and palæontologists is needed. The palæontologist alone can provide certain types of data urgently required for any comprehensive theory of evolution. But as Dr. Simpson points out, the main part of his work in this field is still to do; even with such a well-worked group as the horses "the study of equid evolution has barely begun"! The neo-zoologists can play their part by suggesting what types of investigation are most needed, and later by helping in the interpretation of the results.

Meanwhile biologists will be grateful to Dr. Simpson for a stimulating book, undoubtedly destined to be the parent of much new work and many valuable conclusions.

JULIAN S. HUXLEY.

---

* In connexion with variability, Dr. Simpson's statement that man does not show an unusually high degree of variability would appear to apply to groups within the human species, not to the species as a whole. Further clarification of this point is desirable.

EXPLOSIVES IN WAR AND PEACE

The Science of Explosives

An Introduction to their Chemistry, Production and Analysis. By Prof. Martin Meyer. Pp. xi+452. (New York: Thomas Y. Crowell Co., 1943.) 4.50 dollars.

MODERN warfare calls for the rapid liberation, on an enormous scale, of free nitrogen from organic combination, with a correspondingly swift and lavish release of hoarded energy. This process is brought about through the intermediary of explosives. Contrary to the popular impression, explosives do not administer solely, or even mainly, to the destructive activities of 'the devilish cannon' and its complicated progeny. Explosives do not fade into insignificance in times of peace, although they may forsake the headlines. In the book under notice Prof. Meyer states that in 1940 more than 95 per cent of the total production of explosives in the United States was devoted to various essential activities of peace-time, such as the mining of coal and minerals and the accomplishment of construction work of many kinds. The American peace-time production of 423 million pounds in 1940 underwent a tremendous expansion after the Japanese attack on Pearl Harbour. "A first-class nation," states the author, "may annually use as much as 300,000 tons in peace, and this figure may rise to 3,000,000 tons or more in war."

A little reflexion will show what enormous inroads global warfare is bound to make, for the production of explosives only, upon the world's resources of fats, cotton, and coal, to say nothing of a great variety of other indispensable materials. A little more reflexion will reveal that explosives are not unique examples of discoveries that man has richly misapplied. To take a simpler example, explosives are concentrated forms of fire; and fire, as we know, is a good servant but a bad master. Man must learn to control the application not only of fire and of explosives, but also of thousands of other discoveries and inventions. This means, in the last analysis, that he must learn to control himself. That would be his crowning achievement.

In the work before us, the author offers in a clear and compact form an account of the chief types of explosives, and there are also chapters dealing with more general aspects of the subject, such as the theory of explosive action, grain size and shape, practical explosive and initiatory devices, together with descriptions of the inspection and analysis of explosives and of their application and use. Notes on the packing, shipping, storage, and safety of explosives are followed by a bibliography and index. Much additional information is given in the numerous tables and illustrations. Altogether, the work provides a handy and readable store of information, presented from an American point of view, for all who are interested in the nature, manufacture, properties, analysis, and applications of explosives.

A major criticism applicable to the book is that a specialized treatment of explosives scarcely calls for detailed descriptions, amounting to the best part of two chapters or some 10 per cent of the text, of the manufacture and properties of sulphuric and nitric acids; moreover, it seems unnecessary to include an illustration of a chemical balance, with directions for using it and for calibrating weights, or to devote the whole of four end-papers to a reproduction in duplicate of a table of the atomic numbers and atomic weights of 86 elements. A lack of proportion is shown also in the allocation of only seventeen pages to the important topics of black powder, pyrotechnics, and incendiaries.

Coming to one or two points of detail, it is unorthodox to discuss orientation effects in aromatic nitration under the title of "stereochemistry of the nitro compounds". Also, in spite of a decided paucity of simple expositions of explosives, it is not strictly accurate to claim in the prefatory statement that "there is an absence of material of this kind written in relatively simple and readable style and assembled in one book". What is perhaps the simplest of all such treatments is not mentioned in the lengthy bibliography. JOHN READ.

POTENTIAL THEORY

The Theory of Potential and Spherical Harmonics

By Wolfgang J. Sternberg and Prof. Turner L. Smith. (Mathematical Expositions, No. 3.) Pp. xii+312. (Toronto: University of Toronto Press, 1944.) n.p.

THIS book is the third of a series published under the auspices of the University of Toronto, to meet the ever-growing need for mathematical books in English, which bridge the gap between the elementary text-book and the exhaustive (and often exhausting) treatise.

The important subject about which the authors have taken it upon themselves to write is an example of this nature. Kellogg's "Foundations of Potential Theory" could be regarded as the treatise, in this case, and there are many elementary books in mathematical physics which contain, among their pages, sections and paragraphs (often scattered and badly presented) dealing with those aspects of potential theory necessary for their particular applications. Nowhere, however, until the publication of this volume, was there any connected account, in English, of the subject which could be read as a 'subject-in-itself' by those desirous of making its acquaintance for its own sake.

In spite of the valuable material to be found in its pages, this book just fails to reach the high standard which the authors set out to attain. Within the compass available, it seems undesirable to insist on too much pure mathematical rigour, particularly when the physical aspect has, perforce, to suffer in consequence. Complete and elaborate convergence arguments fulfil an essential role in a treatise or specialized tract in function theory, but those which are merely elaborate, and yet still incomplete, serve very little purpose, especially in a work of this kind. Again, the authors take great care to point out that consistent use of vector analysis is a characteristic feature of their book; but there are very few places where it has been used at all, except to convert a result which has been derived (often unnecessarily laboriously) in some co-ordinate system, into vector notation. Not only is there a large amount of time and space wasted in this way, but the reader also inevitably gets the entirely false impression that the use of vectors in mathematical physics is completely artificial.

As an illustration, the symbol $\partial/\partial n$, denoting differentiation along the normal to a curve or surface, is occasionally written as n. grad; but scarcely ever as the compound operator $\mathbf{n}.\nabla$, whereas it is only in this guise that its real significance as an invariant operator manifests itself.

After a brief introduction on the ideas of vectors and scalars, the book opens with two chapters dealing with Newtonian force fields in two and three dimensions and the corresponding potential functions *in that order*. This, in itself, seems an unfortunate beginning, for in most of the elementary problems in mathematical physics the force fields are calculated *after* the potential has been derived. It would seem to be much more reasonable to define the potential as a line-integral, pointing out necessary and sufficient conditions for its existence, and to deduce from it the vector equation $\mathbf{F} = -\nabla U$; and then proceeding to show at once that the Newtonian inverse square law of attraction is derivable from the potential $U = 1/r$, and finally building up the more complicated functions (for example, those due to doublets, surface and volume distributions, and so on) by the ordinary processes of integration and summation.

Chapter 3 discusses the so-called integral theorems: namely, the theorems of Gauss and Stokes and their various corollaries. It is in this chapter that the authors really fail to give their vector analysis a free hand. It is true that the complete proofs of these theorems present formidable topological difficulties; but as these have been laid aside, in any event, as being outside the scope of such a work as this, there can be no excuse for not presenting simple and elegant proofs along formal lines. Furthermore, the theorems of the equivalent layer (or Green's formulæ) follow much more obviously by vector methods than by the (admittedly equivalent) Cartesian methods used in the text.

In the fourth chapter, the ideas of expansion of potential functions in series of spherical harmonics are treated. Much of the convergence theory could, one feels, be cut out with advantage, as it could be supplied by any competent reader, if so desired. In addition, the more elaborate properties of Legendre's polynomials and the associated functions can only be dealt with, satisfactorily, by complex function theory; and one is left with the distasteful impression that, in certain cases, it is only by luck, rather than judgment, that the correct results are obtained by the cruder arguments involving real variables only.

From Chapter 5 onwards, the book becomes infinitely more interesting, and it is in this and the remaining six chapters that the authors have provided a most valuable contribution to mathematical literature. Chapter 5 gives an account of the behaviour of the potential at points occupied by mass and is sufficiently accurate and comprehensive for most ordinary students. A short chapter on the relations of the two-dimensional theory to that of the functions of a complex variable is followed by a very lucid discussion of the boundary value problems of Dirichlet and Neumann, and a proof of the uniqueness of their solution, if it is assumed to exist.

The problems in the case of the circle and the sphere are solved explicitly in Chapters 8 and 9, by means of Poisson's integral; and certain results from the theory of Fourier series, which arise from these, are provided (with proofs where these can be easily supplied). The theory of Green's function is also most adequately dealt with and the existence of this function is shown to be equivalent to that of the mapping function in the fundamental theorem of Riemann, dealing with the conformal representation of any simply connected region with more than one boundary-point on the interior of the unit circle.

In the last two chapters the existence of the solution of both the boundary-value problems (previously quoted) is shown to be equivalent to th existence of a solution of the various types of Fre holm's integral-equation, of which an excelle account is given in Chapter 10.

In spite of having made so much adverse criticis I think there is no doubt that this book will pro to be of great value as a work of reference. It h been provided with a very detailed table of conten and quite a useful index.

J. H. Pearce.

OPERATIONAL CALCULUS

Heaviside's Operation Calculus Made Easy

By Dr. T. H. Turney. Pp. vii+96. (London: Cha man and Hall, 1944.) 10*s*. 6*d*. net.

The Simple Calculation of Electrical Transients

An Elementary Treatment of Transient Problems i Linear Electrical Circuits, by Heaviside's Operation Method. By G. W. Carter. Pp. viii+120. (Cambridge: At the University Press, 1944.) 8*s*. 6*d*. net

CAN any subject be made easy? Did Silvanu Thompson's "Calculus Made Easy" save single headache in the younger generation when i tried to master the mathematical tools of its elders The first of the above books ought to be one which has been long awaited, namely, a graduated introduction to the powerful tool devised by Heaviside. Th colloquial style does not, however, inspire confidence; and the early analogies, for example, that of a battery and condenser, and a general disregard of physica principles in favour of simplifying or grouping mathematical representations, are apt to lead an innocent reader astray. Just interchanging voltages and currents in formulæ simply will not do, even if this bright idea appears to help in simple applications. If the author's deduction (p. 12) that non-proportionality of current and flux in a laminated inductance leads to the idea that "the term inductance has little meaning in any case" were really true, most electrical engineers would be profoundly grateful. Then in two short paragraphs, which seem to have slipped forward, we are suddenly confronted with the properties of p. We soon come, however, to p and j, Helmholtz's circuit law, and Heaviside's unit function. Through partial fractions we are led to the application of Heaviside's expansion theorem to transmission lines, and to the development of the treatment of impulses. Dr. Turney finally compares Fourier and Heaviside integrals. The author is always on thin ice; although we do not expect rigour in an introduction to a difficult subject, at least we expect discipline. Mathematicians will certainly not commend this book.

The second book has a more restrictive title, although covering a similar section of the subject. The author is on much surer ground, needs no flourishes of style, comes much more quickly to the point at issue, holds on to physical aspects of his problems, and states quite clearly his assumptions of knowledge in the reader; his high-grade examples are closely woven into the text. The student is apt to be diffident in the usage of Heaviside's calculus, except in its simplest applications, in which he often knows the answer from more protracted but less intuitive methods; the present book should through its exercises give students that confidence which is the educational stimulus to go further. Perhaps this is the text-book we have been waiting for.

L. E. C. Hughes.

DIRECT CHEMICAL ACTION UPON NERVE CENTRES IN BIOLOGY AND MEDICINE

By Prof. LENA STERN

Physiological Institute, Academy of Sciences of the U.S.S.R., Moscow

IN the course of evolution, as organisms have become more complex, they have also become more sensitive to their internal environment, for example, in higher animals, to the temperature, pH, and osmotic pressure of the blood and lymph. Minute changes in the properties of the internal milieu may result in serious dislocation of the functioning of the organism. As Claude Bernard said: "La fixité du milieu intérieur est la condition de la vie libre".

Local Environment

In addition to the general internal milieu common to all parts of an organism, there has evolved for each individual organ a specialized 'local' milieu, for which we have proposed the name 'immediate' or 'intimate' environment. Each organ derives the materials necessary for its functioning from the cellular fluid forming its local environment; and into this local environment the organism discharges the products of its metabolism. The physical and chemical properties of the fluid which is the local environment of an organ are related to the structure and functions of that organ. Any abnormal change in the composition of this environment leads to a corresponding disturbance in the organ; the disturbance may be so serious as to bring about the death of the whole organism.

The local environment of each organ is separated from the general internal environment by a physiological mechanism to which we have given the name 'histo-hæmatic' barrier. These barriers regulate the exchange between the blood and the immediate environment of each organ; they control the inward passage of substances from the blood stream; they facilitate the discharge from the local environment of the organ into the blood stream of the products of metabolism; they maintain the constancy of the local environment.

It is clear, therefore, that the proper functioning of each organ depends on the integrity of the histo-hæmatic barrier surrounding its local environment. For example, an increase in the permeability of the barrier would expose the organ to any drugs circulating in the blood, which might not be able to penetrate the barrier under normal conditions.

The Hæmato-Encephalic Barrier

The spinal fluid is the local environment of the brain and the spinal cord. We have found that the properties of the spinal fluid depend largely upon the regulating action of what we call the 'hæmato-encephalic' barrier, which comprises the endothelium of the capillaries and the neuroglia. This barrier protects the central nervous system from toxins, virus, bacteria, etc., in the blood stream; it controls the entry of substances necessary for the nutrition of the central nervous system; it allows the passage from the spinal fluid into the blood stream of metabolic products of the brain which would, if they accumulated, disturb the activity of the central nervous system. The hæmato-encephalic barrier possesses selective permeability not only for substances foreign to the organism, but also for various natural products of metabolism, for example, antitoxins, hormones, etc. The permeability is, moreover, asymmetric: there is more selection in the direction blood→spinal fluid than in the direction spinal fluid→blood. This concept of histo-hæmatic barriers (particularly the hæmato-encephalic barrier) has been the basis of our work on the differences between the effects of drugs injected into the blood stream and into the fluid of the spinal cord.

There is a close relation between the permeability of the hæmato-encephalic barrier for any particular substance in the blood, and the possibility of this substance affecting the central nervous system. The only substances which affect the central nervous system when added to the blood are those which penetrate into the nutritional milieu of the brain, that is, the spinal fluid. Other substances which normally produce no neurotropic effect may affect the nervous system profoundly if they enter the spinal fluid. Consequently, when defining the neurotropic properties of a substance, it is necessary to know whether or not the substance has penetrated the hæmato-encephalic barrier, and been admitted to the immediate environment of the nervous system.

It is of considerable theoretical and practical interest that the selective permeability of the hæmato-encephalic barrier is considerably less in new-born animals with an undeveloped brain (for example, dog, rabbit, cat, rat) than in adult animals of the same species. This is probably true, too, for the new-born human being. This view is consistent with two facts: it is known that the substances introduced for therapeutic purposes into the circulatory system of a new-born child have effects quite different from the same substances in an adult; and the peculiar clinical manifestations of some diseases in the child (cramps, high temperature) are consistent with the view that in the child toxic substances present in the blood pass into the spinal fluid much more easily than they do in an adult. It is our view that there is a parallel development of the central nervous system and the hæmato-encephalic barrier, not only ontogenetically but also phylogenetically.

The defensive action of the hæmato-encephalic barrier not only increases during early development; it also varies according to the physiological condition of the organism. In pregnant animals, for example, the permeability of the barrier is easily changed by chemical or physical agents which scarcely affect the barrier in animals which are not pregnant. Animals heavily drugged with alcohol show, in the same way, a much greater sensitivity of the hæmato-encephalic barrier: in such animals even a slight change of temperature affects the permeability of the barrier.

The selective permeability of the hæmato-encephalic barrier safeguards in health the nerve centres against invasion by toxic substances. But in sickness, the barrier may be a hindrance, because it may prevent the penetration of therapeutic substances to the diseased nerve centres. This view is supported by clinical data. We have evidence that the pathological symptoms of the nervous system in some infectious diseases (for example, tetanus, encephalitis) are due to the direct action of the toxin or virus concerned upon the brain. We have evidence, too, that attempts to cure disorders of the central nervous system by the application of therapeutic agents into the blood stream are ineffectual because the barrier prevents the agents from passing into the spinal fluid.

Direct Introduction of Substances into the Spinal Fluid

There are two ways in which a therapeutic agent can be brought into the local environment of the central nervous system: (1) by lowering the resistance of the barrier (by increasing its permeability) and (2) by avoiding the barrier (by introducing the substance directly into the cavity of the cerebral ventricles).

It is possible through changes of temperature, pH, osmotic pressure, etc., to increase the permeability of the hæmato-encephalic barrier. But the clinical value of this treatment is questionable, for the permeability is increased not only to the substance it is required to introduce, but also to any noxious substances and toxins which may be in the blood stream. The second method, of introducing the substance directly into the cavities of the cerebral ventricles, has been intensively studied by us in recent years. We have, for example, introduced anti-tetanus serum into animals suffering from tetanus. In all experiments where the serum was introduced into the circulation, it gave positive results if introduced before the first symptoms of tetanus appeared. In experiments where the serum was introduced into the cerebral ventricles even after the onset of tetanus, the disease was arrested and there was total recovery: provided, of course, that the interval between the onset of symptoms and the time of injection was not too great.

These results secured with experimental animals have been applied successfully to horses suffering from tetanus and have been confirmed by clinical practice. Patients suffering from tetanus have been injected with anti-tetanus serum by cisternal injection. In the great majority of cases, if the injections were applied in time, the patients improved rapidly. This treatment is now being applied successfully in Army hospitals: simultaneously with an intravenous or intramuscular injection, 10–20 ml. antitetanus serum—that is, 15,000–30,000 American units—are introduced by cisternal injection into the cerebro-spinal canal, after removing an equal volume of spinal fluid. The method has recently been applied by Prof. E. M. Steblov, of the Neurological Institute in Alma-Ata, to treat the after-effects of seasonal encephalitis. Twenty-two cases were treated with reconvalescent serum. In only two of these cases, where the syndrome was of more than twenty years standing, did the injections produce no effect. In the other twenty cases there was visible improvement after the fifth injection, and in some patients even some power of movement was restored.

It is possible that the method may be extended to treat successfully other disorders of the brain and nervous system, even by the introduction direct into the spinal fluid of the patient's own blood serum.

Antagonistic Action of Chemicals

The work of O. Loewi and others has shown that nerve action is accompanied by the production of mediators: chemical substances resembling adrenaline and acetylcholine. These mediators have the same sort of action on effectors as direct stimulation by a corresponding nerve; they support and enhance the effects of excitation on the peripheral parts of the vegetative nervous system.

Our experimental results, and others already published, demonstrate that these mediators have a precisely opposite action on the corresponding parts of the central nervous system. They penetrate t hæmato-encephalic barrier from the blood stream the spinal fluid, and there they tend to neutrali the effect they have produced on the periphe system. These mediators, by neutralizing at one p of the nervous system the effects they have produc at the other pole, provide a means of autoregulati in the organism. Their antagonistic effect is shar by humeral agents, too.

The work of a great number of scientific worke indicates that the metabolites of the brain exert similar autoregulating function. Substances produc in the central nervous system (for example, su stances present in blood flowing from the brai affect the peripheral elements quite differently fro the central nervous system. The conclusion can drawn that these chemical substances, by their co trasting action on different parts of the organis play an important part in autoregulation. The brai controls not only by nervous impulses, but also b liberating chemical agents.

Arising out of this antagonism, there is anoth application of the method of direct injection into th spinal fluid, which depends on the fact establishe by us, that the effect of some inorganic substance (for example, salts of potassium and calcium) on th peripheral elements of the vegetative system an their effector organs differs totally from the effec of the same substances on the central nervous system Thus it has been established that an increase in th quotient K/Ca in the spinal fluid increases the tonu of the sympathetic nervous system; but in the bloo the same changes in the quotient K/Ca lead t diametrically opposite results. It is sufficient t introduce a minimal quantity (a few mgm.) of K ions into the cerebral ventricles to call forth a strong excitation of vegetative organs; augmentation o cardiac activity; increase of muscle tonus, metabolism and excitability: all results diametrically the opposite of those produced if potassium is introduced into the blood stream. The same contrast is brought about by certain other materials (metabolites of organs, hormones, mediators, etc.) when applied to the blood on one hand and to the spinal fluid on the other.

Treatment of Shock

Since many pathological states, including vegetative neuroses, are due to changes in the tonus of the sympathetic and parasympathetic centres, or in the relation between the tonus of these centres, the method of direct application of drugs to these centres has considerable clinical possibilities. The results we have obtained in the treatment of shock in the wounded are of particular interest.

The role of the vegetative nervous system in the development of shock has been developed especially by W. Cannon and his collaborators, and it has been confirmed by many other workers and by ourselves. Shock is directly due to changes in the tonus of the nervous system, in particular to the diminution of the tonus of the sympathetic centres following their extreme excitation. An analysis of the spinal fluid in the later stages of shock shows a decrease in the quotient K/Ca, owing mainly to a decrease in potassium. This is accompanied by a spontaneous decrease in inorganic phosphate. These observations lead us to the conclusion that the first task in the treatment of shock is to introduce potassium phosphate directly into the cerebral ventricles in order to restore the K/Ca quotient.

This treatment proved effective on animals. Soon ter the introduction of the solution, blood pressure creases rapidly, respiration becomes deeper, the citability and reactivity of the animal are restored. he injection must be performed as early as possible cause the capacity of the vegetative centres to spond to treatment decreases during shock. Clinical eatment of shock confirms these experiments. The ethod now being successfully applied to war cases to introduce suboccipitally to the vegetative ntres a mixture of mono- and di-potassium phoshates (6·5 mgm. K per ml., with a pH of 7·4–7·5). or clinical treatment the quantity used ranges from to 7 ml., according to the severity of the shock, and r animals, 0·1 ml. per kgm. live-weight. The atient reacts in one or two minutes. It is essential at the material should penetrate the ventricle vity; failure of the treatment is usually due to chnical errors in its administration.

Other Possible Applications

The results encourage us to suppose that the ethod of direct action upon the nerve centres may e effective in the treatment of other nervous disrders. For example, diseases believed to be due o excessive tonus of the parasympathetic system vagotonia) or of the sympathetic nervous system sympatheticotonia) might be treated by introducing nto the cerebral ventricles potassium phosphate in ne case and calcium salts in the other. Promising esults have been obtained by Prof. Y. Y. Sendulsky f Alma-Ata, in the treatment of certain kinds of eafness associated with the vegetative nervous ystem by cisternal injections of potassium phoshate, and for some kinds of dystrophia and chronic epsis, by injection of vitamin B_1.

A further extension of our investigations in recent ears has revealed that certain metabolites of organs for example, the thyroid gland) affect the nervous ystem in a way quite different from their effects hrough the blood stream. There is an interesting field for the study of the effects of other metabolites on the nervous system. It is possible that, by the use of this method of direct injection into the spinal fluid, some diseases of the nervous system hitherto regarded as incurable may yield to treatment.

PHYSICAL AND CHEMICAL DEGRADATION OF RUBBER

ALTHOUGH chemical unsaturation is not essential to the occurrence of 'rubbery properties', all forms of 'rubber' which to-day find extensive application consist of long-chain molecules with frequently recurring ethylenic linkages. Admittedly, the chemical unsaturation may, and does, have adverse influence on the service life of rubber articles, but it also enables the material to be submitted to various forms of chemical treatment for the fuller control of its manipulation during manufacture and for enhancement of the physical characteristics of the manufactured products. Fortunately, the degree of chemical reactivity is so moderate as to permit a practical compromise leaving a large credit balance on the side of mechanical stability and endurance.

It is difficult to dissociate sharply the phenomena associated respectively with the chemical and physical instability of rubber. They have been of very great importance ever since the inception of the rubber industry. The deterioration of some of his early products was a grievous trouble to Charles Goodyear a century ago, and would have daunted a less pertinacious and resilient pioneer. Thanks to his basic achievements in the United States and to those of Thomas Hancock in Britain, supplemented by other discoveries, the rubber industry has made striking advances, and rubber articles are to-day capable of long service under conditions which then would have been deemed quite impracticable.

The recent achievement of the American chemical industries in producing synthetic rubber on a scale commensurate with the pre-war output of the rubber-plantation areas has incidentally necessitated still greater attention to the deliberate and controlled 'breakdown' of rubber; even more than natural rubber, the chief new material, so-called GR–S synthetic rubber, demands plasticization as a preliminary stage in its conversion into manufactured products.

In view of the many-sided importance of the subject and its associated problems, a symposium was held in Birmingham on May 12, on the initiative of the Midland Section of the Institution of the Rubber Industry, to discuss the "Physical and Chemical Breakdown of Rubber". As stated at the symposium by its chairman, Mr. F. G. W. King, technical director of the Dunlop Rubber Co., the magnitude of the contribution of the rubber industry to the allied war effort is difficult to appreciate fully, and the difficulties which have been surmounted are realized only by those directly concerned. Many of these difficulties fall within the range of the subject discussed.

The nine papers submitted revealed the breadth of the research activities of the industry, three contributions being presented by the British Rubber Producers' Research Association, two by the Research Association of British Rubber Manufacturers, two by the Rubber Division of Imperial Chemical Industries, Ltd., and two by the Technical Department of the Dunlop Rubber Co., Ltd.

The first paper to be read gave a preliminary report by Drs. W. J. C. Orr and J. L. Bolland, of the British Rubber Producers' Research Association, on the "Thermal Breakdown of Rubber" observed with comminuted 'sol' rubber, carefully freed from dissolved oxygen. Up to 200° C., the rubber is stable; but at 220–270° C. it shows gradual degradation without substantial loss of unsaturation but with the formation of a small proportion of volatile products, mainly isoprene and dipentene, approximately one molecule of the former and four of the latter being found when the molecular weight of the rubber, by osmotic measurements, has fallen to half its original value. On further heating, the rubber again becomes more viscous and finally sets to a benzene-insoluble, non-sticky solid. This latter change indicates that the degradation mechanism must be complicated by secondary reactions between the intermediate scission products and other molecular chains. By applying the 'resonance' concept and considering the energy of splitting of the chain molecule at the possible points, it is deduced that both the isoprene and dipentene are formed by fission at the ends of the rubber molecule, little if any of the latter arising from dimerization of pre-formed isoprene.

Details of another piece of fundamental research from the Association's laboratories were given by Dr. L. C. Bateman on the "Photochemical Breakdown of Rubber". When finely cut, purified, *Hevea* rubber in an exhausted silica tube is exposed to light from a mercury arc, formation of a small quantity of gaseous products is observed, largely free hydrogen: the rubber concurrently becomes insoluble, with increase in molecular weight and slight decrease in iodine value. From quantum considerations these results are regarded as being in line with those to be expected from the known behaviour of simpler olefines.

The third investigation from the Associations' Laboratories, described by Dr. E. H. Farmer, related to the "Oxidative Breakdown of Rubber". The first stage in the autoxidative process with rubber involves the absorption of whole molecules of oxygen by the rubber, with formation of unstable organic peroxides; decomposition of these may occur in different ways, but, for natural rubber, gives rise normally to chain scission resulting in softening, with loss of elasticity and strength; whereas for synthetic rubbers it tends to result in toughening caused by polymerization or 'oxygen vulcanization'. For the fuller elucidation of the behaviour of the initial unstable peroxidic rubber product, that of various simpler olefine peroxides was also examined and discussed. The thermal and catalytic acceleration of the decomposition of the unstable 'rubber peroxide' are probably highly important factors in the autoxidative degradation of rubber and demand more intensive investigation than they have received hitherto.

The importance of the promoted degradation of rubber as a laboratory 'tool' was emphasized by two papers dealing with accelerated ageing. "The Heat Ageing of GR–S Vulcanisates" by Dr. J. R. Scott, of the Research Association of British Rubber Manufacturers, was one paper, of two only, devoted solely to synthetic rubber. Dr. Scott reported the results of numerous heat-ageing tests in air or oxygen at atmospheric pressure or higher, and gave due attention to the views of other investigators. The alteration in tensile strength, elongation and modulus of the vulcanizates is found to proceed about 2½ times as rapidly for each 10° C. rise in temperature, which is in agreement with earlier estimates. In contrast to natural-rubber vulcanizates, however, the alteration of GR–S vulcanizates with ageing tends to be less the longer the period of vulcanization; the stability of GR–S towards ageing also appears to be favoured by the use of low proportions of sulphur for vulcanization. Oxidation during ageing is capable of a twofold effect, the predominant result normally being stiffening, presumably by oxygen-bridging of the molecules; with severe oxidation of under-vulcanized samples, however, loss in tensile strength may occur in consequence of chain scission. Hycar EP, another copolymer of butadiene and styrene, shows similar heat ageing to GR–S, but with rather better retention of tensile strength at higher temperatures.

The other paper on accelerated ageing, by Messrs. J. M. Buist and G. N. Welding, of Imperial Chemical Industries, Ltd., dealt with the "Use and Misuse of Accelerated Ageing Tests", and gave a careful survey of the aim of such tests and their limitations as an index to the probable behaviour in service. Permanent alteration in the rubber after ageing, according to circumstances, may concern only a thin skin, or a thick surface layer, or the whole mass. These three types of result were discussed in detail, and appropriate accelerated tests, both by heat-ageing and light-ageing, were brought under consideration. The skin effect is commonly associated with the influence of light. Deep surface effects include atmospheric cracking (apparently initiated by traces of ozone) a surface-hardening or -softening by oxygen attack higher temperatures; the hardening or softening, prolonged, may extend throughout the mass. T authors conclude that the processes leading to t breakdown of rubber are too diverse for all to capable of easy or satisfactory reproduction in single accelerated test. Moreover, for the correct u of accelerated ageing tests, a clear understanding the differences between the types of ageing is essent and each such test should, so far as possible, accelera only one process; for example, that affecting t elongation at break, so that it can be studied indepe dently of others.

Three papers contributed to the meeting dealt wi ageing as caused or induced by exposure to 'weathe The first of these, by Mr. H. C. Harrison, of Imperi Chemical Industries, Ltd., on the "Weathering GR–S", confirmed the paper last mentioned, questioning the general applicability of accelerat ageing tests. Contrary to early indications fro accelerated tests, the weathering characteristics GR–S are disappointing; cracks develop in t material when exposed under slight tension, fresh a and increased air circulation being conducive to s intensified effect; light is not a main cause. Ant oxidants give little benefit, and compounding gene ally provides no satisfactory remedy except for t beneficial influence of a small percentage of certa waxes, particularly those with microcrystalli structure, such as beeswax or paraffin wax. Th problem presented by GR–S rubber was considered b the author in detail not only for stout sheets of th material but also for thin 'proofings' on fabrics.

This subject of atmospheric cracking, in its relation to natural and synthetic rubbers, was dealt wit from a wide angle in a concise and comprehensiv paper by Dr. R. G. Newton, of the Research Associa tion of the British Rubber Manufacturers, entitle "The Mechanism of Exposure Cracking". The rat of 'exposure cracking' (a term which the author prefer to 'atmospheric cracking') is found to be proportiona to the ozone content of the air or ozonized oxyge surrounding the rubber. The normal ozone conten of the outside air is sufficient for the purpose, bu inside buildings it is generally too low. Not only does light not produce cracks, but also it frequently prevents their development by giving rise to an oxidized skin which prevents access of the ozone to the actual rubber surface. Strain is necessary as well as ozone, and, in line with some other investigators, the author agrees that a maximum in the severity of cracking, as judged visually, is observed with an elongation of roughly 20 per cent. The occurrence of this so-called 'critical elongation' is attributed to the mutual interference of neighbouring cracks; cracks formed under the lower elongations join up to form longer and more obvious ones, whereas those formed in more highly stretched rubber tend to remain discrete. Exposure-cracking can be prevented by eliminating strains from the rubber, and cable makers are said to adopt more than one device to this end. Waxes capable of forming a continuous surface 'bloom' on the rubber can afford some protection, but if the film is incomplete, or incapable of self-repair when broken by flexing or further stretching, localized attack may arise with worse results eventually than if no wax had been used.

This importance of complete continuity, if a film of wax bloom, or of any coating preparation, is to give useful protection and not intensified deterioraion, was also stressed in a paper by Messrs. E. F. Powell and V. E. Gough, of the Dunlop Rubber Co. Ltd., on "The Mechanism of Rubber Cracking". While challenging the concept of the existence of a critical elongation', these authors agree as to the oarser and more serious nature of the cracks formed at lower elongations than at higher, although the racks are less numerous in the former case. Consideration was given to the statistical nature of the distribution of the cracks, and several practical aspects of the cracking problem were discussed, such as the distribution of stresses at the bottom of grooves or slits in masses of rubber, for example, in tyre reads, and its influence on the location and direction of crack growth. A parallel seems to exist between the relation of the type of cracking to the probability of attack and to the rate of propagation of previously ormed cracks, and the importance of 'probability of attack' and 'conditional velocity' as revealed in metal-corrosion researches.

The last paper of the meeting, on "The Behaviour of Natural Rubber and GR–S under Repeated Stress Cycles" by Dr. D. Parkinson and Mr. J. L. Bloxham, of the Dunlop Rubber Co., Ltd., recorded results obtained with the Dunlop fatigue-testing machine, which has been described elsewhere. Under repeated cycles of stress lasting over considerable periods, GR–S 'compounds' develop higher temperatures than those attained by analogous natural-rubber 'compounds', but under such conditions they will withstand a higher steadily maintained temperature; so that despite the admitted superiority of natural-rubber vulcanizates in resistance to fatigue, its advantages in this respect are less than might be anticipated from its higher tensile- and tear-strength. Incorporation of carbon black in either form of rubber increases the resistance to fatigue, and 'furnace blacks' have a greater effect than 'channel blacks'. For each type of carbon black there is an optimum concentration which is generally greater for compounded GR–S than for compounded *Hevea* rubber.

In terminating the proceedings, the chairman remarked on the successful issue of the gathering, the first all-day symposium in Great Britain to be devoted to a single group of problems of the rubber industry. The potential value of such discussions and interchange of views between research workers is very great. The full papers and subsequent discussions will be made available in the *Transactions of the Institution of the Rubber Industry*. The Institution will no doubt take steps to ensure that further meetings of similar type are arranged to deal with other outstanding problems.

D. F. Twiss.

VITAMIN A DEFICIENCY AND THE REQUIREMENTS OF HUMAN ADULTS

In response to a request from the Ministry of Food, the Vitamin A Sub-Committee of the Accessory Food Factors Committee (Lister Institute and Medical Research Council) undertook an experiment to obtain information on the human requirement of vitamin A and of carotene. The experiment was carried out at the Sorby Research Institute, Sheffield, for the Medical Research Council, by which it was financed. It lasted from July 1942 until October 1944.

Twenty-three 'conscientious objectors', twenty men and three women, volunteered to live on a diet designed to be deficient in these substances but complete in every other respect. The absence of vitamin A and its precursors was confirmed spectrophotometrically and biologically. Young rats fed on the diet grew well when supplied with vitamin A but, without it, failed to thrive and their livers at autopsy were devoid of vitamin A. The disappearance of carotene from the blood plasma of the deprived volunteers confirmed the absence of these substances from the diet. Prophylactic and therapeutic tests were made with vitamin A and carotene, and fæcal excretion tests were made with carotene from different sources. No attempt was made to differentiate between the biological values of different isomers of carotene.

As the experiment lasted more than two years, the results obtained were extensive and cannot quickly be prepared for publication, but, since their implications in assessing nutritional status and requirements in respect of vitamin A are far-reaching, it is important that some of them should be widely known. It has therefore been decided to publish the chief conclusions about which the team of workers is unanimously in agreement. Full details with a discussion of the literature will appear later.

With efficiency for dark adaptation and plasma values for vitamin A as criteria, none of the sixteen deprived subjects became depleted within a year. Eleven of these continued the test for more than thirteen months, and only three showed marked signs of depletion, after fourteen, seventeen and twenty-two months, respectively. Most of the remainder showed no changes attributable to vitamin A deficiency, except a gradual fall in the plasma value for vitamin A, estimated by the antimony trichloride method; but one failed to show this sign of deterioration even after twenty-two months. The state of the vitamin A reserves of this sample of the population of Great Britain in the summer of 1942 would thus seem to have been sufficient to meet the requirements for from one to two years. This conclusion is in harmony with the finding, at about the same period, of a median value of 600,000 I.U. for the total vitamin A reserves of the liver, determined at autopsy, in cases of accidental death.

Signs of depletion. In the three markedly depleted subjects, the value for vitamin A in the blood plasma declined from about 90 I.U per 100 ml. to about 30 I.U. In the test of the capacity for dark adaptation, measured with the Wald-Steven modification of the Hecht-Shlaer adaptometer, the values for the final rod-threshold ranged, at the start, from 1·55 to 1.95 log. micromillilamberts, and rose to between 2·38 and 3·44; at about the same time, the time of transition from cone to rod vision, which was at first from five to ten minutes, increased to as much in one case as thirty-three minutes.

In contrast with the slow fall in the value for vitamin A in the plasma which occurred in almost all the subjects undergoing depletion, the value for total carotenoids fell quickly and remained low. Chromatography of a pooled sample of plasma after nine months of depletion showed it to contain 18 μgm. total carotenoids per 100 ml., but no measurable amount of α- or β-carotene. The value for the final rod-threshold in all the subjects, whether undergoing depletion or not, deteriorated significantly during the first winter, seven months from the start, but, in most cases, recovered in the spring to the initial level.

The explanation of this phenomenon is unknown, but the risk of misinterpretation thus introduced is clearly great. The value did not again deteriorate significantly until much later, when the plasma value for vitamin A had declined to about 40 I.U. per 100 ml. There did not appear to be any correlation between the value for vitamin A in the plasma and the value for the final rod-threshold until both had deteriorated significantly.

Three different laboratories carried out the blood tests, the samples being distributed by post; their results often varied much for the same sample, but the average of a sufficient number yielded consistent results. All three laboratories agreed that no great reliance could be placed on the result of a single estimation for vitamin A in plasma.

From the thirteenth month of the experiment onwards, P. C. Livingston applied his new technique of rod scotometry to examination of the volunteers. By this method the field of vision was mapped under conditions of dark adaptation with test objects of known very low luminosity[1]. The technique confirmed the existence of defective night vision in the three volunteers whose final rod-threshold was raised and cone-rod transition-time lengthened. In addition, this method revealed the night vision as defective in five of the other deprived subjects who gave normal readings with the adaptometers of Craik and of Wald and Steven. On treatment with vitamin A or carotene, the scotometry readings returned to normal. Rod scotometry thus seemed to detect deterioration of capacity for dark adaptation earlier than was possible by measurement of the dark-adaptation curve.

There were no objective changes on general clinical examination, or conjunctival changes perceptible with the slit-lamp microscope; there were no changes in the blood picture or platelet count. Only one subject showed follicular hyperkeratosis, but a study of the case history indicated that the condition was present from the start and was not specifically affected by variations in the vitamin A supply. There were no definite changes in response to memory and fatigue tests. There was no consistent loss of weight.

Absorption tests. A comparison of the dietary and fæcal carotene for the volunteers receiving a carotene supplement showed that the disappearance of carotene from the gastro-intestinal tract was highest when the carotene was dissolved in fat (arachis oil or margarine); on the average, 28 per cent of carotene given in this form was excreted. The percentage excretion of carotene from green vegetables (cabbage or spinach) was in the region of 60, and from sliced carrots in the region of 75. The individual variations were wide.

Requirement of vitamin A and of carotene. Seven volunteers without previous depletion received, for periods of from six and a half to twenty-two and a half months, a daily supplement of about 2,500 I.U. vitamin A as distilled natural esters in oil, or of about 5,000 I.U. carotene, in oil or from various natural sources, and showed no changes attributable to vitamin A deficiency.

The three subjects who developed defective night vision and low plasma values for vitamin A were dosed with vitamin A or β-carotene in oil while the deficient diet continued. In one case treatment with a daily dose of 1,300 I.U. vitamin A restored dark adaptation and plasma vitamin A values to normal levels within five months. A second case did not respond to a dose of 1,300 I.U. carotene daily but improved in the course of five months when the dose was changed to one of 2,600 I.U. daily. In the thi case, where the degree of deficiency was milder, daily dose of 2,600 I.U. carotene promptly improve dark adaptation and the concentration of vitamin in the plasma.

When the amount of carotene excreted wa deducted, the amount of vitamin A and of caroten which brought about the same result would thu appear to be about the same.

For assessing the requirement the relevant result are the following:

A daily dose of 1,300 I.U. vitamin A or of 2,600 I.U carotene was sufficient to *cure* a mild state of vitami A deficiency. The body reserves of vitamin A, pre sumed as already mentioned to have had a media value of about 600,000 I.U., were sufficient in al sixteen deprived subjects to prevent the onset o definite signs of vitamin A deficiency for from twelv to twenty months; such a reserve would correspon with an average rate of consumption of 1,300 I.U daily for fifteen months.

Thus, inclusion in the diet of a daily dose o 2,500 I.U. vitamin A, or of 5,000 I.U. carotene, may be regarded as adequate for maintenance of norma human adults and as leaving a fair margin of safety

The following members of the Vitamin A Sub-Committee, Dr. K. H. Coward, Miss E. M. Hume (secretary), Dr. S. K. Kon, Dr. T. Moore and Prof R. A. Morton, formed part of a team which included Mr. W. C. Bartley, Prof. H. A. Krebs, Dr. K. Mellanby and Dr. J. Pemberton, each of whom undertook responsibilities in Sheffield and, with Mr. T. W. Goodwin, Dr. H. M. Sinclair and Miss C. M. Wood, participated in the work and in the regular meetings concerned with the conduct of the investigation. Many other workers, whose contributions will be recorded in the full report, supplemented the work of the Sub-Committee.

---

OBITUARIES

Prof. Alexander Fersman

PROF. ALEXANDER FERSMAN, the distinguished Russian mineralogist and geochemist, died on May 20 at the age of sixty-two. The death of his former teacher, Prof. V. I. Vernadsky, a brilliant investigator in the same field, occurred a few months earlier[1]. The double loss is a grievous blow to the science of geochemistry, for both men occupied the leading positions in the vigorous Russian schools of geochemical studies of which a short account was given recently in the pages of *Nature*[2].

For the present notice on Fersman's work, some data have been drawn from a note supplied by Prof. A. Vinogradov, of the Academy of Sciences, Moscow.

Graduating from the University of Moscow in 1907, Fersman first worked in the laboratory of Vernadsky. He was ultimately to become director of the Lomonosov Institute of Mineralogy, Crystallography and Geochemistry in Moscow, a new institute founded in recent years by the fusion of four departments of the Academy of Sciences of the U.S.S.R.

Fersman's early researches were essentially crystallographic and mineralogical: he worked in Paris and Heidelberg and travelled in Switzerland ıd Italy, eventually contributing a paper on the ıineralogy of Elba. He was co-author with V. oldschmidt of Heidelberg of an elaborate memoir a the crystal morphology of the diamond, and later roduced an authoritative treatise on the precious tones of Russia.

In 1912 Fersman was appointed to a professorship ı mineralogy and to a curatorship of the Museum f Mineralogy attached to the Academy of Sciences. 'rom this time his interests were to be devoted to he field of geochemistry. There were to follow during he next twenty-five years his monumental works on eochemistry, and while it is still too early to assess he value of some of the daring theoretical treatment is exuberant genius brought to the interpretation f the factual data, experimental and observational, which he had amassed, his rank as a leader of international reputation has rested on brilliant achievement over a wide field. Between the two World Wars his contributions included detailed investigations on the geochemistry of pegmatites, particularly hose of granite and alkali-syenite type; researches on the geochemical migration of elements within sedimentary terrains remote from magmatic centres, and numerous other studies in regional mineralogy.

Many geological expeditions fostered by the Academy of Sciences within the vast territories of the U.S.S.R. were organized under his leadership, and he personally conducted explorations in Central Asia, the Urals and the Kola Peninsula. These investigations led to highly important economic developments, notably with the discovery of great apatite deposits of magmatic origin in Kola and of large workable deposits of sulphur in the Kara-Kum desert of Transcaspia.

Of Fersman's many achievements, his researches on the great alkali igneous complexes of Khibin and Lovozero in the Kola region rank among the most outstanding. In the elucidation of these unique intrusions, Fersman's own studies were dominant. They have greatly widened our knowledge of the chemistry and mineralogy of alkali magmas and of the conditions controlling the peculiar sodic (agpaitic) type of differentiation.

As director of the Khibin Scientific Arctic Station near Kirovsk, Fersman inspired much of the later work of his younger colleagues in the same field, and it was under their guidance that the participants in the Kola Excursion of the 1937 International Geological Congress were able to appreciate to the full the magnificent pioneer researches linked with his name.

Fersman's most important memoirs, including his works on geochemistry (four vols., 1933–37), pegmatites (1931, 1940) and other studies in regional mineralogy, are in Russian. In English, his "Scientific Study of Soviet Mineral Resources" (1935) provides a succinct account of the planning and development of the mineralogical researches in which he himself played so prominent a part.

In addition to his scientific work—he was author of some five hundred scientific books and papers—Fersman was active in public life. He had a gift for the exposition of scientific knowledge in popular form, and his artistic sense was shown in his articles about chemical elements, minerals and rocks. Member of the presidium of the Academy of Sciences, he was at one time chief editor of its scientific publications.

Fersman was the recipient of a Stalin Prize and was awarded the Order of the Red Banner of Labour by the Soviet Government. Abroad, his honours included foreign membership of the American and British Mineralogical Societies and the award of the Wollaston Medal of the Geological Society of London in 1943.

Sir Martin Forster, F.R.S.

The death in Mysore City on May 24 at the age of seventy-two of Martin Onslow Forster has removed from our midst an organic chemist who, prior to 1922, was an outstanding figure in British chemistry. Forster received his early education at Dover Hill House, Margate, and having decided upon a chemical career he entered the Finsbury Technical College, where he received an excellent training under the late Prof. R. Meldola. As was customary at the time, when the opportunities for research in Britain were somewhat limited, he proceeded to Germany, where he worked at Würzburg under Prof. E. Fischer. The debt which Forster owed to him was in some measure repaid by the brilliant memorial lecture which he delivered to the Chemical Society in October 1920. Returning with his Ph.D. degree, Forster in 1894 came under the influence of Prof. H. E. Armstrong, in whose laboratory he worked as the holder of a Salters' Research Fellowship, and so arose a life-long friendship. His tenure of the fellowship was short, since in 1895 he was appointed by Sir William Tilden to a demonstratorship in chemistry at the Royal College of Science, and there followed a period of amazing scientific activity which rapidly placed Forster in the front rank of British organic chemists.

For many years Forster's investigations were confined almost entirely to the chemistry of camphor, on which subject he published more than thirty memoirs under the general title "Studies in the Camphane Series". Many of these are now only of historic interest; but his work on β-bromocamphor and on the oximes of camphor and *epi*camphor are of lasting value, and the latter form a remarkable contribution to stereochemistry. In 1907, he broke new ground when, in collaboration with H. E. Fierz, the first of a long series of papers on the triazo-group appeared. This work, which was not devoid of personal risk and actually resulted in grievous injury to one of his research students, was actively pursued until 1913, when he resigned his appointment at the Royal College of Science, having been an assistant professor since 1902. Almost all Forster's papers were communicated to the Chemical Society, and they are notable for the clarity and brilliance of their exposition. This latter quality was not confined to the written word, since it was generally regarded as a 'field-day' when Forster read a paper at one of the Society's meetings.

Forster's resignation and his decision to enter politics somewhat surprised his friends, and was undoubtedly due in part to his disappointment at not having been appointed to a full professorship. The outbreak of the War in 1914 brought Forster back to chemistry and in 1915 he was appointed a director of British Dyes, Ltd., a post which he held until 1918. In these critical years he served British chemistry well. His activities were not confined to the technical side of the industry; he was mindful of the importance of social amenities for the staff, being responsible for the first staff club at Huddersfield. During 1918–22 he filled the newly created post of director of the Salters' Institute of Industrial Chemistry, where his experience both as a teacher and in industry undoubtedly proved of the greatest value. His keen interest in the City of London Companies was further shown by his election in 1919 as prime warden of the Worshipful Company of Dyers.

Although so actively engaged in experimental research, Forster found the time to participate in the administration of the Chemical Society. After serving on the Council, he was honorary secretary during 1904–10, treasurer 1913–22 and vice-president 1910–13. The value of his contributions to science were recognized by the Society in 1918 by the award of its highest distinction, the Longstaff Medal. He was elected to the Royal Society in 1905 at the unusually early age of thirty-three, and he served on the Council. He was a regular attendant at the meetings of the British Association, being president of Section B at the Edinburgh meeting in 1920.

A complete change in Forster's life and one made at considerable personal sacrifice came in 1922 when, at the request of his friend Sir William Pope, he accepted the post of director of the Indian Institute of Science, Bangalore. The Institute, which we owe to the munificence of the Tata family, had passed through a somewhat difficult period, and it was clear that if it was to fulfil the hopes of its founders, a director of outstanding quality was required. This it found in Forster, and perhaps in the Institute will be found Forster's most lasting contribution to science. Not only did he win the loyalty and friendship of his staff, but he gained also the confidence and affection of the students. He and Lady Forster, whom he married in 1925, realized to the full their many difficulties. Their hospitality was boundless, and the Institute became a very happy family. His success as a director was due not only to his scientific attainments. He was a fine speaker, and he delighted in the social obligations which his position involved. No one will question that the high position which the Institute has now attained in India is due in large measure to the work which he did.

The many administrative duties of his post prevented Forster from continuing his scientific work in Bangalore, although for the first few years he did direct the work of some research students. But his interest in science never abated, and I personally owe much to his advice and encouragement. He was president of the Indian Science Congress in 1925 and he was an original fellow of the National Institute of Sciences. On his retirement in 1933, Forster settled in Mysore City, making occasional visits to Britain, the last being in 1939. After Lady Forster's death in 1941, his life was somewhat lonely, and he had every intention of returning permanently to London at the end of the War. He had hoped to enjoy once more the scientific life in which he had once played so prominent a part.

J. L. SIMONSEN.

Prof. John Borg

THE death, on May 4, is reported of Prof. John Borg, the most renowned of Maltese botanists. He was formerly superintendent of agriculture, professor of natural history in the University, and director of the Botanic Garden in Malta. From these official posts he retired in 1933; but up to his death he maintained his interests in botany and agriculture, and he held the title of emeritus professor of natural history in the Royal University.

Borg's contributions to the advancement of biolog were varied and included research in both the pu and applied fields. His influence on education wa not limited to his academic activities but extende to public lectures and to articles in the local Pres and other publications written in English or Maltese In agriculture and horticulture, his work include published accounts on the cultivation and diseases o fruit trees in the Maltese Islands, on orange cultur on vines, on scale insects, and on the pig. His boo "Cacti. A Gardener's Handbook for their Identification and Cultivation" (London: Macmillan and Co. Ltd.) is well known and widely used.

The most valuable of Borg's works in systemati botany, and one that will maintain his name amon all interested in the flora of the Mediterranean region is his "Descriptive Flora of the Maltese Islands including the Ferns and Flowering Plants" (Malta Government Printing Office, 1927). This is a boo of 846 pages written in English. It includes a luci introduction to the history of botanical investigatio of the islands, their geology, vegetation and flora The bulk of the volume consists of carefully prepare descriptions of the families, genera and species of th vascular plants, including those naturalized or commonly cultivated, of Malta and the associate islands, together with their Maltese localities an Maltese and English names. The flora gives th impression not only of conscientious preparation bu also of intimate personal acquaintance with the plant described. Malta is intensively cultivated over muc of its surface and almost all the rest is heavily graze (if grazed be the right word) by the almost omnivorou goats, and there is little natural vegetation left; but its flora is surprisingly rich and of considerable importance in studies of the phytogeographica problems of the Mediterranean Basin.

I met Borg only once, in his department in the University of Valetta, and recall him as a quiet, unassuming man devoted to his work but with the widest interest in all that related to his country. His widow, to whom his "Flora" is dedicated and who was his constant companion and assistant on botanical rambles, survives him. His large collection of cacti and other succulents has been left to the Argotti Botanic Gardens and he has made other bequests to his University.

W. B. TURRILL.

Prof. E. Rádl

SOME time in May 1942, Dr. Emanuel Rádl died in Prague at the age of sixty-nine. In early life he was a biologist of local distinction. His critical abilities first reached a wider public in 1909 when he published his "History of the Development of Biological Theories", in which he stressed the changes that had occurred with regard to the significance and the evidence for evolution during the nineteenth century. He was critical of certain Continental schools of biological thought and of various 'cell theories', of temporary 'fashions' in science and of Driesch's ideas on entelechy.

Later Rádl turned his attention to philosophy, changing his chair of biology for that of philosophy at the University of Prague. He wrote several works on the history and modern trends of philosophy, and in his "Present State of Philosophy and Psychology" (1933) he expressed the opinion that Anglo-Saxon countries were then "being infected with the bacilli of moral anarchy, spiritual decadence and cold tellectualism. . . . Who knows how much of our nfusion is due to the fact that England has ceased be the spiritual backbone of Europe ?"

For Rádl the real, the ultimate issue of our life nd our civilization was the problem of whether there an irresistible guarantee and vindication in our earch for truth, whether there is an unshakable inge on which all our ideas, definitions and standards evolve. Rádl was critical but not pessimistic; ndeed, he disliked and attacked the pessimism of swald Sprengler and others. The philosophy of eterminism and nihilism was "one of cowardly bdication and of miserable irresponsibility", but ven in his own country Rádl met with considerable pposition. In 1935 he showed signs of physical fatigue, and it is clear that he foresaw the oncoming catastrophe. He never recovered and the circumstances of his last years hastened his end.

G. Druce.

We regret to announce the following deaths:

Sir Peter Chalmers Mitchell, C.B.E., F.R.S., secretary of the Zoological Society of London during 1903–34, on July 2, aged eighty.

Mr. F. Oates, O.B.E., chief geologist in Tanganyika Territory, on June 10, aged fifty-six.

Dr. H. C. Redeke, the well-known Dutch authority on hydrobiology and fishery research, on April 10.

NEWS and VIEWS

National Physical Laboratory for India

The committee appointed by the governing body of the Council of Scientific and Industrial Research, India, in February 1943, to prepare a scheme for the establishment of a National Physical Laboratory for India has now issued a tentative report setting out the scope of the proposed laboratory, and the staff, equipment and finances required to establish it. Such an institution is regarded as of fundamental importance both for the development of scientific research and for the promotion of organized industries in India, which possesses no metric, electrical, optical or other physical standards which can claim statutory acceptance or scientific precision. The National Physical Laboratory, Teddington, has served as the model for planning an Indian National Physical Laboratory, which as envisaged by the committee will consist of eight sections: weights and measures; applied mechanics and materials; heat and power including low-temperature work; optics (including spectroscopy and photography); electricity (including magnetism, X-rays and radioactivity); radio, sound and electro-acoustics; building and housing research; and shipbuilding and navigational research. Separate institutions for aerodynamics and metallurgy are to be established in India, and accordingly such sections are not included in the proposed Laboratory.

Besides standardization work, the proposed Laboratory should undertake investigations relating to the survey, standardization and processing of primary resources and also fundamental research, and will provide facilities to university teachers for research during the vacations and also to research workers engaged in industry. It will serve as a vital link between the universities and industry. The proposed scheme contemplates the establishment of a Central Specifications Board modelled on the American Federal Specifications Board, which will undertake the formulation of specifications with the aid of the National Physical Laboratory in India and in consultation with consumers, producers and other interests. The report contemplates special grants for pilot plant and emphasizes the importance of having a fully equipped laboratory from the commencement. The emphasis is placed on equipment as much as on the permanent staff or its work, for the Committee considers that a central research station, partly or wholly supported by the State, should be in a position to help any industry requiring facilities for solving problems of immediate interest, besides serving as a repository of general knowledge and carrying out long-range research which will ultimately benefit the whole of industry.

United Nations Relief and Rehabilitation Administration: European Agriculture

The importance of an early improvement in the food situation in Europe is stressed by the inclusion of an agricultural rehabilitation officer in every mission sent by the United Nations Relief and Rehabilitation Administration to the continent of Europe. Missions have been at work for some time in Greece and have more recently entered Jugoslavia and Czechoslovakia; another is preparing to leave for Poland. A special observer has been sent, at the request of the Dutch Government, to Holland. At the first council meeting of the Administration, the organization was charged with the duty of assisting governments in liberated areas in providing the supplies and service needed to enable farmers to sow and harvest essential crops, maintain dairy herds and rehabilitate farms. To this end the Administration may help in re-establishing experimental stations and essential agricultural institutions, organizations and services. The rehabilitation of fisheries is also within the scope of the Administration's activities. Its assistance has already been requested for the re-equipment of veterinary laboratories in Czechoslovakia, Jugoslavia and Poland, and of the Marine Biological Institute in Greece. It is also pressing for immediate facilities to be granted to the International Office of Epizootics in Paris for the resumption of its valuable work in collecting and disseminating information on the occurrence and spread of epizootic disease, and in general on animal health and the means of preserving it. One of the duties of the agricultural officers of the Administration is to inquire into the state of agricultural, scientific and technical research in the country to which they are accredited, and to suggest where a study of results already obtained in the free world, or possibly the visit of a British or American specialist, might help in the solution of local problems.

National Parks in the United States

The National Park System of the United States appears to be in a healthy and progressive state. A review of its position in recent years is contained as one section in the Annual Report of the Secretary of the Interior for 1944 (Washington, D.C.: U.S.

Printing Office. 45 cents). Rather less than one per cent of the total continental area of the United States comes under the care of the National Park System. In 1944 several small additions were made, but the only one of considerable size was in Texas, and the one of most interest was the home of F. D. Roosevelt, which was classed as a historic site. There were war-time difficulties to be faced. Two parks in particular were threatened by economic needs. A threat to the Sitka pines in the Olympic National Park, which were wanted for aircraft production, was averted by supplies from British Columbia and by the increased production of aluminium. Red spruce and hemlock of the Great Smoky Mountain Park were spared by alternative supplies for paper-making being found. Drought conditions in the spring of 1944 raised a demand for the Californian parks to be opened to cattle grazing, but the Parks Committee, after a full inquiry, did not feel justified in granting the request. The demand, however, is to be renewed. In spite of war conditions, the national parks have remained open to visitors and have been much frequented.

Map of British Isles

A COLOURED map of the British Isles, designed to illustrate several aspects of their geography, has been published as a reprint from a Polish volume compiled under the editorship of Dr. Z. Holub-Pacewicz (Glasgow: Księżnica Polska). A brief commentary and the legend, both in English, explain the chief features. The small scale, 1 to 3,000,000, limits the amount of detail and necessitates many generalizations. Perhaps the most noteworthy feature is the analysis of the structure and relief of the coast-line. Eight different types of coast-line are indicated by different colours and symbols. Surface relief is shown by layer colouring, and a few names are given, but, except for the scarps of the south-east, there are no indications of structure. The more important towns are shown with indications of size, but there seems to be a little confusion in the use of the term 'conurbation'. Lost towns in plenty are indicated off the East Riding coast and a few off the Lancashire coast, but none elsewhere. The chief railway lines are marked. The notes accompanying the translated commentary include references to suitable reading, so that the book should help to achieve its object of giving Poles some idea of Great Britain.

Protection of Timber against Powderpost Beetles

ALL who have had anything to do with timber in tropical or semi-tropical regions will have become acquainted with the work of certain boring beetles, or powderpost beetles as they have been termed, of the family Bostrychidæ; posts and sawn timber of most broad-leaved trees are liable to severe damage. The chief damage is done by the larvæ feeding on the sap wood, as is well known. Research and experiments have been carried out in more than one part of the world, with the view of discovering some cheap and practicable method of protecting wood from this type of pest. In leaflet No. 69 (Entomology) of the Forest Research Institute, Dehra Dun, preliminary tests of two methods of protecting timber are dealt with. They are intended to give temporary protection when more standard treatment such as impregnation with preservatives cannot be applied because of lack of plant or material. A mixture of creosote and fuel oil, applied externally, definitely prevents attack for at least nine months and probably longer. A coating of lime gave complete protection over a period of three months when liability to attack was most serious. It is expected that provided the coating is kept intact, protection will be permanent. In each case, it is emphasized that treatment must be applied within a short period of cutting or sawing.

Fluorescence Microscopy of Tubercle Bacilli

Aparato Respiratorio Y Tuberculosis (9, No. 4, Oct.–Dec. 1944, published in Santiago De Chile) has a paper with the title "La Microscopia Fluorescente En La Investigacion Del Bacilo Tuberculoso" contributed by Dr. B. Juricic, Sr. Nicolás Vuskovic, Drs. Gastón, González, Hernán Durán, and Hipólito Vergara In this they describe the results of their investigation of 5,044 cases in which samples of expectoration and gastric contents over a period of a year and a half were examined by the fluorescence microscope. The accessories utilized for transforming the microscope into a fluorescence type were those manufactured by the Spencer Lens Co., Buffalo, and consist of an electric bulb of low voltage and high amperage, provided with a blue-violet filter, and in addition, of an aluminized mirror with a yellow filter for the eyepiece. A monocular microscope was found more satisfactory than a binocular, the number of prisms in the latter considerably diminishing the fluorescence. The results are shown in two tables and a third supplies comparative figures for the Ziehl-Neelsen method. The advantages of the fluorescence method are obvious from this comparison; 52 per cent greater positive results being obtained than with the Ziehl-Neelsen method. In addition, less time is spent in staining the specimens, there is greater rapidity in the examination, and the use of oil immersion is avoided. It is claimed that the fluorescence microscope has a brilliant future before it and that its efficiency is susceptible of great improvement in various ways.

An Electrical Moisture Meter

IN a paper read on April 20 before the Institution of Electrical Engineers in London, Dr. L. Hartshorn and Mr. W. Wilson first outline the purpose which moisture meters are intended to serve, and the various types which have already been described, and then describe the development and construction of a new type of meter that has already been put to good use in several industries. A constant alternating voltage is applied to a sample of the material contained in a small vessel, which may be regarded as a fixed air condenser, or in some instances as a conductivity cell. The current passing through the material is measured by means of a sensitive thermionic ammeter of special construction, which can be adjusted to read the capacitance current, proportional to the dielectric constant of the material; the conductance current, proportional to its A.C. conductivity; or some function of both these currents. The current selected is that which shows the most favourable variation with moisture content. The use of the meter for testing seeds and grain, dried foods and flax straw is discussed, and typical results are given, together with a brief outline of other applications.

Determination of Time Corrections

THE Astronomical Institute of the Academy of Sciences of the U.S.S.R. has issued an "Ephemerides for the Determination of Time Corrections by Equal ltitudes (Zinger's Method) for 1944". The method mployed is similar to that used for 1941, a description f which appeared in *Nature* (153, 29; 1944). The orresponding volume for 1945 has also been received.

"Annuaire Astronomique de l'URSS pour l'An 944", published by the Astronomical Institute of he Academy of Sciences of the U.S.S.R., has been eceived at *Nature* office. It follows the usual proedure, giving the spherical and rectangular co-rdinates of the sun for each day referred to the ean equator and equinox of 1944.0 and 1950.0, he right ascension and declination of the moon and lanets, mean places of stars, 1944.0, etc., with an xplanation at the end in which references are made o various pages of the volume; a brief outline of he formulæ and methods of computation employed s given.

mperial Chemical Industries Fellowships at Cambridge

THE following candidates have been elected to mperial Chemical Industries Fellowships at Cambridge, the subject of research being indicated in brackets: *Physics:* Dr. C. J. Birkett Clews (analysis by X-rays of the structure of conjugated monomeric ydrocarbons at low temperatures, and of the structure of highly polymerized and allied compounds); Dr. M. F. Perutz (structure of crystalline proteins and related substances by X-ray analysis); Mr. M. Ryle (radio physics). *Chemistry (Physical, Inorganic and Organic):* Dr. J. N. Agar (mechanism of electrochemical oxidation and reduction); Dr. J. Baddiley (chemistry of nucleotides); Dr. K. Bailey (studies on cytoplasmic nucleoproteins and nucleic acids); Dr. P. Johnson (investigation of macromolecular systems by gravitational and diffusion methods). *Engineering:* Mr. A. H. A. Hogg (plasticity).

Institution of Electrical Engineers Awards

THE Council of the Institution of Electrical Engineers has made the following award of premiums for papers read during the session 1944–45, or accepted for publication: Group A. *Kelvin Premium:* Mr. G. F. Shotter; *John Hopkinson Premium:* Mr. R. J. Halsey. Group B. *Non-Section Premiums:* Mr. H. Frohlich (Ayrton Premium), Mr. G. A. Juhlin (Llewellyn B. Atkinson Premium), Dr. R. Pohl (Extra Premium). *Installations Section Premiums:* Mr. R. O. Ackerley (Crompton Premium), Mr. R. T. Lythall (Swan Premium), Mr. L. S. Atkinson (Extra Premium). *Measurements Section Premiums:* Dr. L. Hartshorn and W. Wilson (Silvanus Thompson Premium), Mr. D. J. Desmond (Mather Premium), Mr. H. J. Josephs (Extra Premium). *Radio Section Premiums:* Prof. Willis Jackson and Mr. J. S. A. Forsyth (Duddell Premium), Dr. K. R. Sturley (Ambrose Fleming Premium), Mr. D. G. Fink (Extra Premium). *Transmission Section Premiums:* Mr. D. B. Irving (Sebastian de Ferranti Premium), Messrs. W. Kidd and E. M. S. McWhirter (John Snell Premium), Mr. R. C. Hatton and Dr. J. McCombe (Extra Premium), Mr. J. L. Carr (Extra Premium). Group C. *Fahie Premium:* Messrs. R. B. Armstrong and J. A. Smale. *Paris Exhibition, 1881 Premium:* Messrs. L. J. C. Connoll, O. W. Humphreys, and J. L. Rycroft. *Overseas Premium* (for senior members): Mr. R. H. Paul. *Students' Premiums (value £10):* Mr. W. M. Butler, Mr. G. B. Downham, Mr. J. R. Hanchett, Lieut. L. B. Knowles, Mr. J. Willis. *Students' Premiums (value £5):* Mr. J. Banks, Mr. H. Burton, Mr. T. E. Calverley, Mr. J. B. Higham, Mr. A. C. Robb, Mr. W. B. Robertshaw.

Thomas Gray Memorial Trust

THE Council of the Royal Society of Arts offers a prize of £50 and an award of £50 under the Thomas Gray Memorial Trust, the objects of which are "The Advancement of the Science of Navigation and the Scientific and Educational Interests of the British Mercantile Marine". The prize is open to any person of British or Allied nationality for an invention, publication, diagram, etc., which is considered to be an advancement in the science or practice of navigation, proposed or invented by himself in the period January 1, 1940–December 31, 1945. Competitors must forward their proofs of claim between October 1 and December 31, 1945, to the Acting Secretary, Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2.

The award of £50 is made to a member of the British Merchant Navy for any deed which is of outstanding professional merit. The period to be covered by the offer will be the year ending September 30, 1945, and the judges will consider their decision on or after January 1, 1946.

Travelling Fellowships in Medicine

THE Medical Research Council announces that preliminary arrangements have been made for the resumption of Rockefeller Medical Fellowships, to be provided from a fund entrusted to the Council by the Rockefeller Foundation of New York. These fellowships are intended for graduates resident in Great Britain who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. It is hoped it may be possible to make a limited number of awards during the academic year 1945–46, depending on the availability of candidates and facilities for travelling.

Announcements

AT Oxford on June 28, the honorary degree of D.C.L. was conferred on Sir D'Arcy Thompson, professor of natural history in the University of St. Andrews.

The Osler Medal for 1945 has been awarded to Dr. C. G. Douglas, University reader and demonstrator in general metabolism.

MR. N. B. KINNEAR, deputy keeper in the Department of Zoology of the British Museum (Natural History), has been appointed keeper in succession to Mr. M. A. C. Hinton, who retired on June 29.

THE Jones-Bateman Cup is offered triennially by the Royal Horticultural Society for original research in fruit culture which has added to our knowledge of cultivation, genetics, or other relative matters. Particulars can be obtained from the Secretary of the Society, Vincent Square, Westminster, London, S.W.1.

REFERENCE was made in *Nature* of June 23 (p. 764) to the Association of Special Libraries and Information Bureaux, but an old address was given; the present address of the Association is 52 Bloomsbury Street, London, W.C.1.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Individual Hæmoglobins

It has been known for a long time that whereas living tissue can be successfully transplanted from one site to another in an individual animal, transplantation from one individual to another of the same species does not succeed[1,2]; it has been shown that the red blood corpuscles of individual cattle[3] and fowls[4] can be distinguished from one another by immunity reactions; and it has been pointed out that every individual of a sexually reproducing species is genetically different from every other individual, except in the case of identical twins[5]. Such phenomena must depend upon chemical differences between individuals, particularly between their proteins, and in point of fact differences have been found between the hæmoglobins of individual animals.

Several workers, in analysing the globins of mammals, have reported differences between individuals[6]. C. G. Douglas, J. B. S. Haldane and J. S. Haldane[7] showed that the relative affinity for carbon monoxide and oxygen of the bloods of individual mice differs, and this implies hæmoglobin individuality. Anson, Barcroft, Mirsky and Oinuma[8], using the Hartridge reversion spectroscope, found individual variations in the span (that is, the difference between the wave-length of the axes of oxy- and carboxy-hæmoglobin α-bands) for rabbit, mouse and horse; these differences (not given in the text, no doubt since they were not pertinent to the main research, but deducible from their Fig. 6) again mean individually different relative affinities for carbon monoxide and oxygen.

Using the Hartridge instrument, I have lately determined the axial wave-length of the α-band of oxyhæmoglobin in a number of earthworms and frogs without finding any individual variation within the species, but all of four individual rabbits studied were found to be different from one another. The two most diverse, which were of the same sex, age and colour, differed by 3 A. To be certain that the difference was not due to plasma, red corpuscles were suspended in saline and centrifuged before being laked in distilled water, but the result was unchanged. Measured again with fresh blood a fortnight later, the result was still the same. Since individual rabbits thus have visibly different hæmoglobins I looked next for the same phenomenon in human beings. With the view of getting the greatest differences, if there were any, I studied a West African Negro, a Chinaman, a Chinese woman, an Austrian Jew, an Englishwoman and myself. In all these cases the oxyhæmoglobins were identical as regards the wave-length of the α-band.

The Hartridge spectroscope, with which the axis of the oxyhæmoglobin α-band can be measured to one Ångstrøm unit with an error of about one unit on either side, is a very delicate instrument, and a number of precautions are essential in using it. The apparent wave-length varies with the intensity of absorption; it is therefore necessary each time to use the same blood concentration, which may be matched spectroscopically with a standard dilution of human blood. Successive measurements are seldom identical; in my work, series of ten measurements were therefore made and the mean taken. Th calibration of the instrument varies very slightl from day to day, however carefully it is handled this may perhaps be due to temperature or to change in the observer's eye, but, whatever the cause, th calibration of the instrument should be checke whenever it is used and this can be done quite simpl with the 5853 neon line, which is near the oxyhæmoglobin band. The results of Litarczeck and Dinschiotu[9] with human blood are so strange that I ca only ascribe them to spectroscopic errors. These authors used the Hartridge instrument but sa nothing of precautions such as I have just enumerated They found that seven normal human beings had fiv different oxyhæmoglobins, the extremes of which were 8 A. apart, and five anæmic subjects ha four oxyhæmoglobins with extremes 23 A. apart Moreover, in the course of three months the wave-length changed in one individual by 10 A.

I thought it so important to establish beyon doubt the reality of the difference between my extreme rabbits, a difference not far from the experimental error, that instead of taking only ten readings I took seventy with each blood. It is undesirable t take more than twenty readings at a time as the ey becomes fatigued and the readings scattered, and fo this reason I rested after every twenty readings which were taken in alternate groups of five readings with each blood. Moreover, half the measurements were made on one day, half on the next day with fresh blood. The means and standard errors for the two rabbits were 5771·9 ± 0·2 and 5775·2 ± 0·2 Ångstrøm units, the difference between 5772 and 5775 being thus statistically significant and the reality of visibly different individual oxyhæmoglobins established. It would be of interest to know if such differences are genetic.

A Sympathomometic Pressor Substance in Animal Organ Extracts

During a quantitative study of the piperidine content of various animal organs, following the identification of this substance as a normal constituent of urine[1], it was observed that most organs contain considerable amounts of a pressor substance different from piperidine.

The active substance was obtained by continuous fluid extraction with ether of extracts of the following organs: liver, spleen, kidney, heart, lung, voluntary muscle, smooth muscle (intestine), brain, pancreas, testis. No pressor activity was found in extract from human placenta. As a rule, the pressor action was preceded by a fall of short duration in blood pressure on intravenous injection in the cat.

A preparation with a pure pressor effect was obtained when the ether solution used to remove fats and lipoids from the organ extracts was extracted with a 10 per cent sodium sulphate solution. After removal of the inorganic salts by precipitation with alcohol, the activity corresponded to about 0·1–0·5 μgm. adrenalin per gm. of fresh tissue in spleen extracts. Further yields were obtained by repeated extraction of the organ extract with the ether solution of lipoids and extraction of this solution with a salt solution. In the remaining primary organ extract the biological action corresponded to 2–10 μgm. adrenalin per gm. of fresh tissue.

The active pressor substance is dialysable and readily soluble in water and alcohol and also to some extent in a mixture of alcohol and ether. It is quickly destroyed by heating in normal alkaline solution, but is relatively stable to acids.

The biological actions of the purest preparations so far made are as follow: a rise in blood pressure of the cat in chloralose anæsthesia, enhanced by cocaine and reversed by ergotatime; inhibition of the isolated rabbit's intestine and the non-pregnant uterus of the cat after atropine, and stimulation of the isolated rabbit's uterus, and the frog's heart.

The biological reactions point to a sympathomometic substance, and one is led to consider its relation to the "*sympathicusstoff*" of Loewi. The active extracts give colour reactions with ferric chloride of a similar kind to adrenalin and a strong Folin-Cannon-Denis' reaction with phosphotungstic acid. It has not been possible to obtain the colour reaction with iodine, however, though added adrenalin readily gave this.

Presence of Reddish Pigment in Eggs and Ovarioles of the Desert Locust, and its Probable Phase Significance

I noticed some time ago that in the desert locust, *Schistocerca gregaria* (Forskål), several eggs had a reddish tinge owing to the presence of pink pigment superficially on the egg-chorion, while others lacked this pigment. Generally, in an egg-pod all the eggs are either pink or non-pink, though exceptionally both kinds may occur in the same pod. Hatchings from some 185 pink eggs (from five different egg-pods) and 406 non-pink eggs (from ten different pods) gave the following kinds of first-stage hoppers: (*a*) Pink eggs: 54 per cent *gregaria* (black pattern), 22 per cent intermediate and 24 per cent *solitaria* (green); (*b*) non-pink eggs: 25 per cent, 17 per cent and 58 per cent respectively. These proportions suggest that pink eggs produced a majority of phase *gregaria* hoppers, though it must be mentioned that hatchings from five pods (172 eggs) were contrary to this suggestion.

I also noticed that in some adult females the ovaries have, at the base of many ovarioles, a mass of orange-red pigment lying in the small basal follicle or pedicel which connects the ovariole proper with the egg-calyx. This pigment was found in both *solitaria* and *gregaria* adults and in both 6- and 7-eye-striped individuals (Roonwal[1]), but was absent in fourth- and fifth-stage hoppers. It was also observed in adults of the rice grasshopper, *Hieroglyphus nigrorepletus* Bol., from a *microptera*. The fact that both the egg and ovariole pigments are soluble in acetone and acetic acid, weakly soluble in absolute alcohol, and insoluble in water, 40 per cent formaldehyde and glycerine, suggests their close similarity. Presumably the ripe eggs, while passing through the pedicel during oviposition, become invested with the reddish pigment.

Pink-red pigments play a considerable part in the desert locust. Künckel d'Herculais[2] first noticed it in the body-wall of young adults from swarms, while Johnston[3] showed that the pink occurs only in the *gregaria* phase, the *solitaria* adults not acquiring it at any stage. Chauvin[4–8] has further studied the adult pigments and also shown that a red pigment is ejected with the excreta. In *Locustana* and *Locusta* Faure[9] has suggested the presence of a hypothetical substance, *locustine*, which is responsible for phase production and which can be transmitted from one generation to the next through the medium of the egg-substance. In view of the similarity, as shown above, of the reddish pigment of eggs and ovarioles, the suggestion may be made that this pigment is connected with Faure's *locustine*.

Full results will be published elsewhere.

'Palolo' Worms in Pacific Waters

Commander Burrows' interesting letter[1] on the palolo worm prompts me to confirm his assumption that this annelid occurs elsewhere than in Fijian and Samoan waters. It exhibits a similar periodic rising at three points off the coast of Ulawa Islands in the Solomons, where its name is 'orku'[2], and it has also been observed from southern Espiritu Santo in the New Hebrides[3]. Specimens which I sent to the British Museum in 1936 from Ulawa were identified by Mr. C. C. A. Munro as *Eunice viridis* Gray, and this is clearly the same as the *Eunice virida* of Commander Burrows.

In Fiji the mbalolo was reported from Vanua levu as long ago as 1936[4], so that this can be added to Ovalau and the Yasawas. As a matter of interest, a resident on Ovalau recently reported[5] that no worms were recorded at Tokou in 1943; but they were seen in the Yasawas and at Savusavu, Vanua levu, in October and November 1943.

A Factor in Clover Nodule Formation Associated with the Volume of the Medium Occupied by the Roots

In the course of experiments involving the growing of clover seedlings (Late-flowering Montgomeryshire Red) on agar medium in test-tubes, it was noticed that the number of nodules produced per plant depended upon the number of individual plants occupying the same tube. As the nodule bacteria were present in very large numbers, this variation in nodulation cannot be due to paucity of organisms; indeed the question raised is rather why so few nodules are formed on plants in spite of the massive infections of the root hairs which are known to occur[1].

Experiments to elucidate both these questions are being carried out and a short report of the first result obtained is presented here.

Clover plants were grown in tubes (6 in. × ⅝ in.) on slopes of a 1·2 per cent agar medium previously sterilized, containing mineral salts but deficient in nitrogen, and inoculated with nodule bacteria. The experiment was arranged in such a way that the number of plants sown per tube and the volume of agar medium was varied. The number of nodules produced per plant was counted after a period of 120 days, and the mean number of nodules and the volume of medium per tube are entered in Table 1.

TABLE 1. MEAN NUMBER OF NODULES PER PLANT.

Volume of medium per tube	1 plant per tube	2 plants per tube	3 plants per tube
4 c.c.	20·4 ± 2·0	9·3 ± 1·9	5·3 ± 1·1
8 c.c.	34·9 ± 3·7	16·1 ± 3·4	12·1 ± 3·1
12 c.c.	31·5 ± 4·6	23·5 ± 6·3	14·4 ± 2·3

It will be noted that for each volume of medium used the number of nodules per plant is inversely related to the number of plants in the tube. Further, the mean number of nodules per plant increases with the volume of medium per tube and is roughly proportional to the volume.

Assuming that these relations are such that: (1) the nodule number is proportional to the volume of the medium, and (2) is inversely proportional to the number of plants present, it is possible to calculate the expected number of nodules for each variant from the mean number of nodules per plant over the whole experiment. The calculated values are entered in Table 2, and with the single exception of the entry for one plant in 12 c.c. medium, the agreement between expected and observed values is very satisfactory.

TABLE 2. CALCULATED MEAN NUMBERS OF NODULES PER PLANT.

Volume of medium per tube	1 plant per tube	2 plants per tube	3 plants per tube
4 c.c.	16·4	8·2	5·5
8 c.c.	32·7	16·4	10·9
12 c.c.	49·1	24·5	16·4

The simplest hypothesis that this effect is due to direct competition for nutrients has been shown by later experiments to be inadequate to explain the results given above. That the effect is also not due to delay in nodulation is shown by the figures for mean leaf number at the time of primary infection in Table 3.

TABLE 3. MEAN LEAF NUMBER AT PRIMARY INFECTION.

Volume of medium per tube	1 plant per tube	2 plants per tube	3 plants per tube
4 c.c.	1·94 ± 0·10	2·31 ± 0·13	2·02 ± 0·07
8 c.c.	2·31 ± 0·22	2·25 ± 0·17	2·54 ± 0·20
12 c.c.	2·18 ± 0·20	1·72 ± 0·23	1·79 ± 0·09

With regard to the question of the comparativel few nodules formed on the root system in any treatment, the generally discarded hypothesis is revive that the nodule is a metamorphosed lateral roo and that the maximum number of nodules is determined solely by the potential number of lateral roo primordia present in the primary and secondar roots. In the course of this work selected lines o plants have been secured displaying large variation in nodule number under conditions already described In such cases the rate of increase in nodule numbe agrees strikingly with the rate of lateral root production in control uninoculated plants, but not wit the rate of increase in total length or extent of the root system. It has further been shown that diminution in nodule number following crowding of plants in a given volume follows closely the reduction of lateral roots under the same conditions.

In the absence of detectable competition effects as a clue to this specific volume relationship, it appears probable that the phenomenon can be attributed to some nodule- and lateral root-inhibiting excretion from the roots, the concentration of which varies with plant number and the volume of the root medium.

Experiments to test this hypothesis are now under way.

Laue Photographs of Sub-crystalline Regions in 'Hybrid' Crystals of Potassium Dihydrogen Phosphate

ATTENTION has recently been directed[1] to the break-up of single crystals of Rochelle salt and of potassium dihydrogen phosphate (KH_2PO_4) into crystal 'hybrids' when these substances are cooled below their transition points. A similar phenomenon has now also been established by means of Bragg photographs in the case of potassium dihydrogen arsenate (KH_2AsO_4).

A number of novel features about the size and mutual relationships of the sub-crystalline regions within a 'hybrid' single crystal (cf. ref. 1 and Fig. 2) has been observed by means of Laue photographs. Fig. 1 shows portions of Laue photographs of potassium dihydrogen phosphate below and above the transition point. For these exposures, the crystal was mounted at the centre of a cylindrical camera, with the *c* axis vertical, and with the (100) face approximately at 37° to the beam of white X-rays. Below the transition point (Fig. 1, *a*), the Laue reflexions from the hybrid are split into two, three or four components according to their indices. Fig. 1 (*b*) was taken without changing the position of the crystal, some hours after its temperature had been

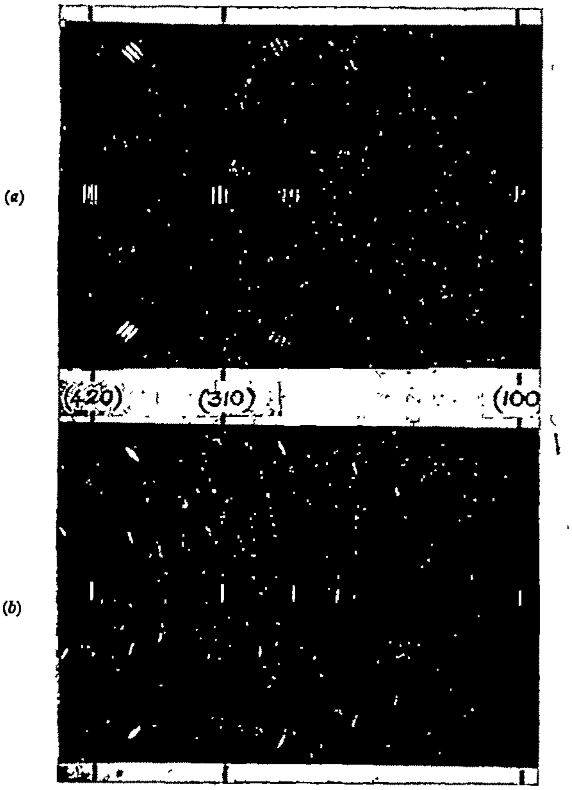

Fig. 1. LAUE PHOTOGRAPH OF KH_2PO_4. (a) AT APPROXIMATELY − 183° C. (b) REPEAT EXPOSURE WITH IDENTICAL ORIENTATION AFTER 18 HOURS AT ROOM TEMPERATURE.

raised above the transition point. The components of the split reflexions have merged to give the pattern of the original single crystal.

From these split Laue reflexions, interesting information can be obtained about the mutual relationships between the sub-crystalline regions within a 'hybrid' single crystal, about the size of the regions, and about the time required for the change from hybrid to single crystal and back again.

The fact that single Laue reflexions above the transition point are split into a finite number of components, rather than spread into a broad band, when the crystal changes to a hybrid, implies that the sub-crystalline regions of lower symmetry assume only a limited number of directions with respect to the original tetragonal axes. In general, a ($hk0$) reflexion is found to split into four components, when $h \neq k \neq 0$. The separation of these components varies with the ratio h/k, and the (100) and (010) show three components only, whereas the (110) shows only two. This can be accounted for by the fact that keeping the c axis the same, a sub-crystalline region of lower symmetry can be produced in four distinct orientations with respect to the original framework, and yet preserve one of its axes in common with the a or b tetragonal axes of the original single crystal (cf. Fig. 2).

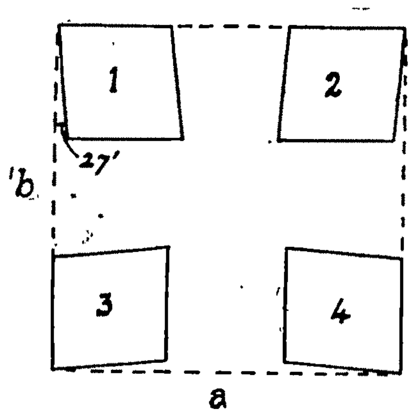

Fig. 2. POSSIBLE POSITIONS OF SUBCRYSTALLINE UNITS IN THE HYBRID WITH RESPECT TO ORIGINAL CRYSTAL AXES. (1) AND (2) a AXIS UNCHANGED. (3) AND (4) b AXIS UNCHANGED.

Information about the size of the sub-crystalline regions can be obtained from observations on the relative intensities of the components of a split reflexion. The intensities of each of a pair of components corresponding with orientations (1) and (2), or (3) and (4) of the units (cf. Fig. 2), are found to be the same, showing that the crystal as a whole remains electrically neutral. But in general, the intensity of one pair may be notably greater or smaller than that of the other. If the portion of the crystal illuminated by X-rays were of about the same size as, or smaller than, a single sub-crystalline unit, only one of the four components would be observed for any given setting of the crystal. On the other hand, if the portion of crystal illuminated were so large as to contain very many units, statistical smoothing would lead to equal intensities for all four components. In actual fact, with the sizes of crystals and X-ray beam used, the relative intensities of the components lie between these two extremes. From this, a provisional estimate of the size of the sub-units is about 5×10^{-3} cm. side.

Finally, Laue reflexions permit some estimate of the time of reversion from a hybrid to a true single crystal, when the temperature is raised above the transition point. With some crystal specimens, this change is completed within a few minutes at room temperatures. With others, hysteresis is more marked and split reflexions can be observed which coalesce after a few hours to give the pattern of a single crystal (Fig. 1).

Afterglow Effects in High-Pressure Gases

WE have recently demonstrated[1] the existence of afterglows following intense spark discharges in argon, hydrogen and other gases at pressures of 1–2 atmospheres. The submission of this further note, in advance of a more detailed publication[2], is prompted by Lord Rayleigh's recent experiment[3] and Jabłoński's comments[4]. The recent work of O'Doherty[5,6] is also relevant.

Experiments with square current-pulses indicate that afterglows persist after the cessation of current flow. Fig. 1 shows an oscillogram of the current wave for a discharge across a 0·5 cm. gap between tungsten electrodes in hydrogen at 18 lb./sq. in.

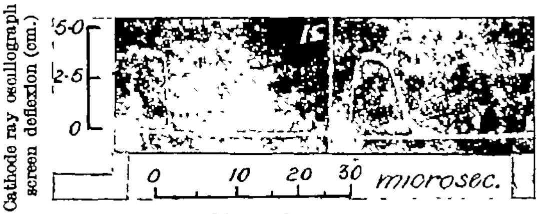

Fig. 1. Fig. 2.

pressure. The light output from the discharge, as recorded by a photo-electric electron multiplier, is shown in the oscillogram of Fig. 2. An afterglow of short duration, about 2 microsec., is observed, which was not observable in our earlier rotating mirror experiments[1] with damped condenser discharges.

The afterglow in hydrogen is explained by us[2] as due to the finite thermal capacity of the spark channel, leading to the delayed emission of light by electron/ion recombination, by the simple thermal excitation process, or by a combination of both effects. Radiationless three-body collisions are also probably of importance, since the ion densities in the spark channels are very high (10^{17} ions/c.c. or more).

Lord Rayleigh[3] showed that afterglows of about 10 microsec. were observable with electrodeless discharges in hydrogen at 0·2 mm. pressure and, despite the calculated rise in gas temperature of about 38,000° due to the extremely high instantaneous power dissipation in the discharges, no interpretation of the results was given. It was pointed out, however, that the time of persistence (about 10 microsec.) of the Balmer lines was about a thousand times as long as the life of the excited states in question.

In our experiments the spark channels were fairly sharply defined, so that estimates of surface area, rate of heat loss, etc., can be made[2]. It is found that the thermal time constant is of the order required to explain Fig. 2, and although it is difficult to make similar calculations for Lord Rayleigh's tube, it is considered likely that the afterglows observed with it can be explained in the same way. The persistence of the Balmer lines for times greater than the normal life-time of excited atoms is therefore to be expected. Jabłoński's suggestions are to be supported, with the important addition of thermal excitation as a means for providing delayed emission.

The experiments are being continued and extended in several directions[7] with increased accuracy, in particular to decide the relative importance of the various effects responsible for afterglows and to investigate spark channels and other transient gas discharges.

Allotropic Modifications of Diamond

THE relationships which exist between the structural symmetry of a molecule and its spectroscopi behaviour have been fully worked out by Placzek[1] One result of his theory is that if a molecule has th symmetry of the crystallographic point-group *Oh*, th activity of its vibrations in infra-red absorption an in light-scattering are mutually exclusive. On th other hand, if the molecular symmetry is that of th point-group *Td*, every vibration of the triply degenerate class must appear both in light-scatterin and in infra-red absorption, or else be absent i both.

Placzek's theory is applicable, *mutatis mutandis*, t the spectroscopic behaviour of crystals in respect o their fundamental lattice vibrations. The consequences of it mentioned above afford a straightforward explanation of the remarkable fact that while all diamonds exhibit in light-scattering a intense line with a spectral frequency shift of about 1,332 wave numbers, the corresponding infra-red absorption appears only in some diamonds, but not in others. This difference in spectroscopic behaviour is, in fact, a complete demonstration of the existence of allotropic modifications of diamond and shows further that the forms more commonly met with showing the infra-red absorption have only tetrahedral symmetry of structure, while the less common variety, in which the absorption is absent, has the full symmetry of the cubic system.

The crystallographers of the nineteenth century (for example, Groth[2] and Miers[3]) who, on the basis of the observed crystal forms, assigned to diamond the lower or tetrahedral symmetry, recognized it as a necessary consequence that two variants of it, namely, the positive and negative tetrahedral forms, must exist, and explained the comparative rarity of forms clearly exhibiting the lower symmetry as the result of their interpenetration. Apart from the crystallographic evidence which supports this explanation, there is an array of experimental facts concerning diamond established by my work and that of my collaborators[4], which proves that such an interpenetration does really exist in diamonds having tetrahedral symmetry of structure. The evidence can be summarized in the statement that while the characteristic infra-red absorption goes hand in hand with various other physical properties, for example, blue luminescence, ultra-violet opacity, feeble but sharply defined classical X-ray reflexions and small photo-conductivity, all these properties themselves are highly variable, and that such variations are perfectly correlated with each other. The interpenetration of the positive and negative tetrahedral structures in different degrees and the resulting variations of structure afford a natural interpretation of these facts.

The existence of two sub-classes *Oh* I and *Oh* II in the octahedral division is also indicated by the highly characteristic laminated structure parallel to the octahedral planes which is characteristic of this type of diamond, and which readily reveals itself under the polarizing microscope. The observed structures cannot be explained on the basis merely of a random irregularity or mosaicity of the crystal lattice. Indeed, the high intensity of X-ray reflexions characteristic of this type of diamond is definitely associated with its laminated structure, as has been clearly demonstrated by the X-ray topographs of Mr. G. N. Ramachandran[5]. Finally, it should be marked that the appearance of geometric patterns cleavage plates of diamond exhibiting the local ariations in the various physical properties mentioned above is a convincing ocular demonstration f the fact that we are really dealing with distinct llotropic forms of diamond, as also with the consequences of their interpenetration and/or interwinning.

The above statement of the case is by way of reply o Mrs. Lonsdale's letter published in *Nature* of ebruary 3 last. She does not discuss the array of acts brought forward in the symposium but hallenges' what she refers to as a 'speculation' on he basis of certain minor aspects of the X-ray ehaviour of diamond, which are not really fundamental to the issues under consideration. Mrs. onsdale believes that the specific points mentioned y her controvert the main thesis established by the ork of my collaborators and myself; this is not so. As the present letter, however, is already of sufficient ength, a detailed examination of those points must e reserved for a separate communication.

Infra-Red Spectrum of Diamond

The new theory of crystal dynamics put forward by Sir C. V. Raman[1] leads in the case of diamond to the result that the atomic vibration spectrum of this crystal should exhibit eight distinct monochromatic frequencies. Of these, the mode of highest frequency (1,332 cm.$^{-1}$) corresponds to the triply degenerate vibration of the two Bravais lattices of carbon atoms with respect to each other, and this is active or inactive in infra-red absorption according as the crystal structure of the diamond possesses tetrahedral or octahedral symmetry. The other seven frequencies represent oscillations of the layers of carbon atoms parallel to the faces of the octahedron or the cube occurring normal or tangential to these planes, with the phase reversed at each successive equivalent layer. By the nature of the case, such oscillations should be *inactive* in the infra-red absorption as fundamentals; but owing to anharmonicity, the octaves of these frequencies should be capable of appearing in infra-red absorption. Besides the octaves, various combinations of these frequencies would also be active in infra-red absorption.

A detailed exploration of the infra-red absorption band exhibited by diamond in the region of wavelengths between 4 μ and 5 μ was made by Robertson, Fox and Martin[2], using a concave grating of one metre focus of echelette type, in conjunction with a prismatic instrument. The investigation showed that the band had an observable fine structure; indeed a whole series of sharply defined peaks or absorption maxima was noticed, the positions of which were capable of exact measurement within a few wave-numbers.

These results must be considered surprising on the basis of the older theories of crystal dynamics, according to which the vibration spectrum of a crystal is essentially a continuous one. Indeed, it is not easy to see how any explanation of the experimental facts could be offered on the basis of those theories. On the other hand, they find a natural explanation on the basis of the new dynamics as explained above.

Both in the earlier investigation of Robertson, Fox and Martin[3] and the later one mentioned above, the two most conspicuous and sharply defined absorption peaks are those at wave-numbers 2170 and 2028. These agree within a wave-number or two with the octaves of 1088 and 1013 respectively which represent the frequencies (determined by other spectroscopic methods) of the atomic vibrations normal to the octahedral planes. The other peaks in Robertson, Fox and Martin's curve may also be explained quite accurately as allowed combinations of the lattice frequencies.

Shear Modes in Non-Piezo-Electric Crystal Plates

Recently we described a new method[1] for the determination of the elastic constants of crystals, utilizing ultrasonic waves of continuously varying frequency. At that time, it was thought that the method would not permit the thickness transverse vibrations to be detected. The full set of elastic constants could be obtained only after supplementing the work by a few static torsion observations.

Further work has now revealed that these transverse or shear modes can also be transmitted through crystal plates and communicated to liquids in the form of consequential longitudinal strains. Associating such transmission maxima with thickness transverse frequencies, torsion constants for crystal plates can be calculated and the full set of elastic constants obtained by purely dynamical methods. This result has now been used for checking previous measurements on some crystals and to make new measurements on others. Full details and the numerical results are being published elsewhere.

It may be pointed out here that this observation is analogous to that of Bhagavantam and Suryanarayana[2], who have recently demonstrated that besides the usual longitudinal ones, shear modes also can be excited in piezo-electric crystal plates and transmitted to liquid media as corresponding longitudinal waves.

COMBINED RAW MATERIALS BOARD

THE third annual report of the Combined Raw Materials Board covers the year ended January 26, 1945, and shows clearly that the international planning of the production and distribution of industrial raw materials, the world demand for which exceeds the supplies available, will long be required. The progress of the War during 1944, and the completion in large measure of the major planning tasks in the raw materials field in support of the war effort, permitted the two member Governments to review the Board's duties and terms of reference and to consider what modifications might be necessary in future.

The Board was designed as a war-time organization; but it is encouraging to learn that it has been decided, as a result of these discussions, that the Board shall continue in being for the duration of the War against Japan, and to operate under its existing terms of reference and with the increasing collaboration of the other United Nations most closely concerned. The text of a joint public announcement of January 19, 1945, which covers also the Combined Production and Resources Board and the Combined Food Board, is appended, and should remove the fear of any hasty jettisoning of the war-time machinery of economic partnership and control, and of the liberated countries of western Europe seeking to outbid each other or their more prosperous neighbours for scarce materials by independent buying in the markets of the world.

The report indicates a general improvement in 1944 in the raw materials position, and stringencies were arising less from shortages of raw materials than from other factors, particularly the shortage of labour for processing raw materials. The Board has been able to relax close control over certain grades of asbestos, balata, balsa wood, cobalt, mercury, mica, molybdenum, shellac, tantalite and tungsten, but on the other hand, sudden and unforeseen changes in the demand and supply position made it necessary to restore close control of antimony and zinc. Combined action was also necessary to deal with new shortages of jute, platinum, lead, casein, animal glue-making materials and goatskins, and the report refers to the way in which changes in military requirements and the needs of newly liberated countries prevent the guarantee of equilibrium. The acute dearth of natural rubber and of hard hemp persisted, and the Board urges that the conversion from the use of natural to the use of synthetic rubber should be vigorously pursued in all consuming countries. The situation with regard to hides and leather steadily worsened during 1944, and is likely to be one of the most serious facing the Board during 1945. Arrangements have already been made to bring the United Nations Relief and Rehabilitation Administration and the governments of Europe financing their own reconstruction requirements into close working arrangements with the Board to ensure that the orderly flow of hides may continue as new claimants against the world's supply enter the picture.

Particularly during the latter half of 1944, the governments of the liberated areas were in constant consultation with the Board regarding their requirements of essential raw materials, and although no substantial deliveries were possible before the end of the year, these claimants may cause new stringencies in raw materials available for civilian use in t United States, Great Britain and elsewhere duri 1945. Within the narrower range of scarce commo ities such as hides and leather, lumber, paper a pulp, cordage fibres, jute and lead, the legitima needs of Europe will curtail the quantity available f others, although on the other hand the industri output of western Europe should soon help counteract the current deficits in such items as tyr and textiles.

MICROFILM AND OTHER MEAN OF DOCUMENTARY REPRODUCTION

AT the nineteenth annual conference of t Association of Special Libraries and Informati Bureaux held in December last, it was felt that justi could not be done to the photographic reproducti of documents by microfilm and other methods witho a special conference on this subject alone. Such conference was therefore held in London in the roo of the Royal Society during June 1–2, under t auspices of the ASLIB Microfilm Service. Its thr sessions drew a full gathering of some hundred an fifty librarians and other workers in bibliographic fields, including many from government department and a number of representatives of the photograph industry. The first two sessions were devoted large to technical matters related to copying and reprodu tion processes, and the third and last session to th vexed question of copyright. At all three sessions th vigour of the discussions, quite as much as the hig quality of the contributions of the principal speaker provided a measure of the value of the conference and if little was achieved in the way of proposals fo that standardization which would do more tha anything else to promote the use of this valuable ne tool—a tool destined, some maintain, to transform research library practice—the conference did succee in demonstrating the variety of purposes for whic document-copying by photographic means is needed, and in suggesting some of the directions in which advances are likely to be most rapid.

After a brief speech of welcome had been made by Prof. A. V. Hill, who presided over the opening session, Mr. F. J. Tritton (of Ilford Limited) gave a clear and admirable survey of the principal photographic methods of document-copying and of the technical problems they involve, illustrating his remarks by reference to full-size paper reproductions, by the various processes, of a page of an ordinary journal comprising letterpress and illustrations in line, stipple and half-tone. For satisfactory reproduction of typographic matter, some overall gain in contrast is generally considered desirable, and while this does not affect the clarity of line and stipple illustrations, it gives poor reproduction of half-tone blocks. A compromise is therefore necessary, and since the greater bulk of material normally copied is purely typographic, materials of relatively high contrast are generally preferred; their development can, when necessary, be so modified as to reproduce half-tones satisfactorily. The processes can be classified as (*a*) those needing a camera, yielding records either substantially full-size (for example, photostat, using paper) or of reduced size (microfilm), and (*b*) those requiring no camera, but employing straight contact-printing to give a full-size copy, among these ng reflex processes, applicable to documents nted on both sides. Any of these processes can be de to yield a negative (the sole copy) or an limited number of positives (from a master negave). The choice of process depends much on the lume of work to be done, since gross costs are viously affected by the cost of the apparatus needed making the copy and in using it; it depends also the purpose of the work, since evidently if reduced ulk is important, whether for storage or transport, me such method as microfilm is essential.

Other processes were mentioned in the course of an nimated discussion, among them in particular being he 'micro-print' processes which have recently tracted considerable attention, especially in America. case in point was the 'micro-card' system which as been described at length by Fremont Rider, brarian of the Wesleyan University Library, in The Scholar and the Future of the Research ibrary" (see *Nature*, **154**, 655; 1944). Rider, impressed by the average rate of growth of American search libraries, which, he finds, double in size every xteen years, has proposed that the back of the pical 5 in. × 3 in. library index card should carry reduced image of up to one hundred pages of the xt of the document catalogued; and thus, in short, at the research library of the future would be oused *on the back* of its catalogue cards, the cards hemselves being produced at a cheap rate and in elatively large editions by central reproducing gencies. Mr. Tritton believes that a special difficulty f this and other micro-print systems using high egrees of reduction, quite apart from the present ack of satisfactory reading apparatus, is the obliterating effect of dust-particles settling during the copying of the original or in the course of printing. ther micro-print processes were mentioned in discussion, including one by Dr. Carl White of Columbia niversity, by which reduced copies of 25 pages of n original are offset-printed upon a single printed age of normal size.

Notwithstanding these developments, micro-film remains at present, in Great Britain and the United States, the medium most widely used for bulk reproduction work. A very pertinent discussion, therefore, was prompted by the second paper of the conference when Mrs. L. Moholy (director of the ASLIB Microfilm Service) reported on discussions she has had with Dr. L. A. Sayce on the important practical questions: whether perforated or unperforated film should be used, and whether a fixed frame-length should be adopted or a frame-length varying, at a fixed degree of reduction, with the length of the original document. Unperforated film offers greater economy in film area and therefore in weight, and has been employed by the ASLIB Microfilm Service, much of the output of which has been sent overseas. On most technical grounds it has much to commend it, but difficulties have arisen because unperforated film cannot be passed through the sprocket-driven apparatus which has for the most part been used in Britain.

An interesting discussion led to a suggestion that in future ASLIB should supply perforated film unless unperforated be specifically requested, since the former can be used in any reading apparatus. Similar divisions of opinion were clearly shown on the question of fixed frame *vs.* varying frame. The majority of speakers favoured the former, which simplifies apparatus problems (automatic selection of frames in reading and analysing machines) and makes for ease of filing and indexing of short lengths of film, though it can be somewhat wasteful of film when the page size of the originals varies.

A similar diversity of present-day practice was seen in the field of reading apparatus, described by Mrs. L. Moholy in an illustrated lecture on "Projectors and Reading Machines" at the second session of the conference. The discussion showed, so far as a synthesis of the diverse needs of different classes of user is at all possible, that the ideal microfilm reader would probably be a relatively light and portable apparatus giving an easily readable image projected on a white reflecting surface (rather than on a diffusely transmitting screen), the apparatus being adapted to take a film bearing images either along or across its width and having conveniently operable means of changing from one frame to another and of selecting a desired frame as quickly as possible, and at the same time taking up so little space on a desk as to leave plenty of room for notebooks, etc. If we add that the apparatus would have to be produced cheaply because, it was urged, the average research user would want a reader on his desk and not merely in the central library of his department, we realize that no such reader exists as yet. Reference was made in discussion to a small cheap folding reader made of cardboard, adapted to take a few frames of film, which was used during the War for supplying information to the F.F.I. in France, the folded card reader and the microfilm being dropped from the air.

It was stated by some speakers that most users of microfilm services prefer to have prints which can be read direct, and while this may be due in part to the lack of really satisfactory readers, there is no doubt that a print which can be filed for easy reference has many advantages for the research worker. The storage of microfilm and its resistance to wear were also mentioned. Work carried out in the United States and elsewhere has shown, Mr. Tritton said, that provided the photographic processing has been properly carried out, the age of a microfilm record should be at least as great as that of the original document. Exposure to tropical atmospheric conditions should be avoided by air-conditioning film-storage compartments, but such steps are not necessary in temperate climates. As to wear in the course of handling, that appears to depend on the care taken by the user; but Mrs. Moholy emphasized that master copies should not be used in readers.

During this second session of the conference, at which Dr. C. H. Desch took the chair, Mr. G. R. Edwards (secretary of the Royal Society of Medicine) gave an account of the microfilm service which has been provided since the outbreak of war by that Society, as a means of providing its overseas members with information on request. It had been widely used, also, by the Director General of the Army Medical Services. Mr. Edwards pointed out that microfilms not only occupy a much smaller space than photostat copies, but also cost considerably less. It is certain that in future any library of standing will have a film reader and should be ready to use every type of technical device to disseminate its material. The use of such devices should, therefore, be taught in courses on librarianship.

The final session of the conference was in the form of a 'brains trust' on documentary reproduction and copyright, with Mr. G. S. W. Marlow, barrister-at-law (secretary of the Faraday Society), as chairman and question-master. The 'brains trust' consisted of

Prof. J. D. Bernal, Mr. E. J. Carter, Dr. Arundell Esdaile, Dr. C. H. Desch and Mr. R. A. Lochner. The chairman opened the proceedings with a summary of the relevant parts of the law of copyright. The making of a photographic copy is obviously "reproduction of the original" within the meaning of the Acts, but since the Acts permit "fair dealing" with an original for the purposes of private study and research, the problem raised by photographic reproduction is largely "When is dealing fair ?" In the course of the answers to this question, in which the audience shared freely, Prof. Bernal thought that scientific workers have long been breaking the law not only for study but also for criticism. To him, "fair dealing" implied the question: Was the photocopying service one for which money could reasonably be asked by the owner of the copyright ? If the copies were made for the use of one or two persons only, it would be very different from copies made for class-teaching on a large scale. Dr. Esdaile amplified this by saying that fair dealing ceased when the commercial interests of the owner were injured. Mr. A. G. Dance, of the Ministry of Education, said that the matter is one of great consequence, and some decision must soon be reached because the Ministry was hoping to see a very considerable increase in the use of film strip after the War. Several speakers urged the advertising value of photocopies. If production of photocopies, so far from reducing the demand for the original, stimulated such a demand (as has happened with the B.B.C. in the concert field), then injury to the owner of the copyright could scarcely be said to have occurred. Mr. Tritton went further, stating that the authors of much of the material now being microfilmed are individual scientific men and other professional workers whose greatest reward lies in the wide dissemination of their works, for which they rarely receive payment in money. Mr. Chilton added that the copying of individual articles in journals puts these articles at the disposal of research workers who only in rare instances could be expected to subscribe to the original journals, especially when account is taken of the widespread scatter of material on any one subject throughout the thousands of current scientific and professional periodicals. It was generally agreed, however, that since publishing bodies are inevitably business concerns, copyright problems cannot be got round in this way.

Dr. R. S. Hutton and Mrs. Moholy pointed the way to a solution of the problem, first referring to present U.S. practice whereby the purchaser of a photocopy declares that he will not use the copy other than for the purpose of private study, and secondly calling for a less cumbersome arrangement with the owners of copyright than the present one, which requires that in cases of doubt the copying agency has to make contact with the owner before proceeding with the copying. Time-saving being one of the greatest advantages of photocopying methods, it is desirable to have an automatic arrangement with copyright owners concerning the terms under which they are prepared to permit photocopying. It would then be possible for a copying agency like ASLIB to carry out its work without specific reference to publisher or author in any particular case.

It has been impossible in the course of a brief review to cover the many interesting points arising from this conference, but it is understood that the proceedings will be available in due course.

L. V. CHILTON.

BRITISH MUSEUMS DURING TH WAR YEARS

"THE great task of museums and art galleries this country during the War is to help preser the basic sanity of our peoples and anything that c be done in this respect will be of greater ultima value than most of us perhaps can now realize These words are quoted from a message from Maj S. F. Markham to members of the Museums Associ tion in 1940. How the museums and art galleri have endeavoured to carry out this task is the subje of the leading article entitled "Endeavour ar Achievement", appearing in the *Museums Journal* April 1945. The information contained therein based upon the many museum and art gallery repor received regularly at the offices of the Museun Association in London.

The author states that the large majority of thes institutions have not only continued their activiti throughout the war period, but also that they ha considerably risen in public appreciation; that the development, far from being curtailed by war cond tions, has been greatly accelerated; and that "th support of museum and art gallery activities is no accepted as a normal service in any progressive cit or town". Some of the causes leading to this sati factory position are to be looked for in the popula short-term exhibitions of material supplied b government departments, the Council for the En couragement of Music and the Arts, and many othe organizations; the co-operation of the museums an art galleries with government departments and th various Services in the provision of instruction fo men and women in the Forces, and of loan-exhibit to camps, canteens and clubs; the arrangement made for discussion groups, concerts and art exhib tions; the many informative exhibits and talk dealing with the need for fuel economy, paper salvage food production and so on; and the special caterin for the needs of leisure and thought by carefu presentation of artistic, historical and scientifi material.

That the need for such amenities is very real i proved by the overwhelming response of the public wherever they are provided, and the results fully demonstrate that where the service is well rendered there will it be well received—indeed, even demanded. Nevertheless, the high attainments of even a majority of institutions must not be allowed to mask the fact that there are still far too many areas in Great Britain where the museum service is static, in decay, or even non-existent. Further, reports from even the larger museums continue to stress the need for expansion, better staffing, better working facilities, and more adequate expenditure; and there has been much criticism from not unimportant quarters. Even the writer of the article outlined above is aware of such matters, for he writes, ". . . it is of paramount importance that museums and art galleries should turn their present proud position to good account when peace returns. Directors and curators should take their rightful place in the circle of leading professional men and women who render notable service to the community". And again, "The Museums Association is staking a general claim for the advancement of museums and art galleries throughout the country, but local authorities must adapt this according to their individual needs". At this point, however, one may doubt whether *all* local authorities e sufficiently interested in, or informed of, this rticular public service, and hence whether they are ualified to come to any conclusion at all about such eeds'. One more statement from the article under nsideration is worth quoting for the light it throws pon a not uncommon official attitude towards useums: "Museums have been the Cinderellas of e services for too long a time". It is evident, erefore, that many of these institutions are at resent in a state of suppression, and that the cause ay be ill-informed, ungenerous, or timid rule. It is vident, also, that various authorities, whether they re responsible for the conduct of a museum service r not, have yet to be convinced of the value of the useum in the fields of education and research, and n the intelligent and constructive use of leisure.

HISTORICAL LIBRARY OF YALE UNIVERSITY SCHOOL OF MEDICINE

THE difficulties of scientific libraries, the meagre funds sometimes allocated to them and the devoted labours of those who work obscurely in them or the benefit of science are often not adequately ppreciated by those who would be the first to maintain that libraries are essential tools of research. It would, indeed, do most undergraduates and esearch workers in science departments no harm to work for a month or two in a library; for only those who have sufficient imagination can realize, without his practical experience, all the labour and organization which goes to the making of an efficient library ervice. One record of this kind of service is given in the reports for the years 1941–44 of the Historical Library of Yale University School of Medicine (Sterling Hall of Medicine, New Haven, Connecticut).

During the first year (1941–42) this Library, which was endowed by Harvey Cushing and dedicated on June 15, 1941, made vigorous efforts to build up its collections, especially those relating to the medical history of the War of 1914–18; the Library is also associated with the work of the National Research Council's Subcommittee on Historical Records of the medical history of the present War. The same Council financed the publication of a classified bibliography of aviation medicine prepared by the Yale Historical Medical Library, supplements to which have been requested by the National Research Council's Sub-committee. The problems which occupied this busy year are discussed in these reports. One of the Library's most useful decisions was that books should be available on loan without restriction, and many scholars outside Yale have benefited from this. Another valuable service is the opening of the Library for seven days a week.

The Library's outstanding treasures are the collection bequeathed to it by Harvey Cushing himself and the other one bequeathed by Dr. Arnold Klebs, who died in 1943 in Switzerland, where his books await transportation to Yale. These collections will place Yale in the forefront of libraries concentrating on fifteenth-century literature. To them the Library can add, among its other treasures, the collection of Prof. J. F. Fulton relating largely to the seventeenth century. Prof. Fulton's other devoted services to the management and general policy of the Library as chairman of its Advisory Board are evident throughout these reports. He is also consultant to the Army Medical Library, the system of classification of which the Yale Library now follows. Another feature of the Library's work has been the lectures and demonstrations given each year by Dr. Arturo Castiglioni. The Library has issued the catalogue of Harvey Cushing's collection, which has been considered the finest gift of books by a medical man since William Hunter left his library to the University of Glasgow. Cushing's collection is rich in documents on the anatomy of the Renaissance, the surgery of Tudor England and Vesalius' books. The great historical Library now being formed at Yale is a fine memorial to Cushing, and under the care of Prof. John Fulton and his colleagues it will fare well. G. LAPAGE.

MARINE ECOLOGY IN SOUTH AFRICA*

PROF. T. A. STEPHENSON and his assistants have studied intensively the intertidal fauna and flora of South Africa for many years, and the result is a valuable series of ecological memoirs. In Part 1 (1939) of this paper, an account was given of zonation in the intertidal belt surrounding South Africa, to which were added details of the distribution of the Patellidæ. The present part describes the distribution on the South African coasts of the more important intertidal species, and defines the geographical components of the fauna and flora. A third part is to be published later which will include, among other items, a comparison of results with those of other workers.

A very large amount of work is entailed in this survey, and the results are of great interest. Altogether a coast-line of about 1,820 miles has been surveyed and about 1,200 species identified. The most important forms on which attention has been concentrated number 318 (202 animals and 116 algæ).

The intertidal fauna and flora comprise four components—a very large warm-water component supreme in the east but dying down westward; a smaller, but important, cold-water component, paramount westward but diminishing eastwards; a component centred about the south coast, disappearing to the eastward and westward, and a component consisting of species which occur around the entire coast from Durban to Port Nolloth. In addition there appear to be components of more local range centred about different parts of the coast.

Two very large elements are included; one endemic or indigenous to South Africa, the other consisting of species with an East African, Indic or Indo-Pacific range. Apart from these, other elements (Atlantic, sub-antarctic, cosmopolitan, etc.) are represented in relatively small proportions. The number of species rises steadily from west to east.

A comparison of the zonation of these coasts brings out roughly a *Littorina* zone, recognizable throughout although the species of *Littorina* change from east to west; a Balanoid zone throughout, everywhere inhabited by *Patella granularis* as well as by barnacles, but westward the barnacles diminish leaving the Patella dominant; a zone of *Patella cochlear* throughout the greater part of the coast; but at both the eastern and western ends complications appear due to the diminution of that species and the consequent dominance of other forms; and the lowest zone, the sub-littoral fringe, is also demonstrable throughout though its population changes and it becomes rather vague to westward, where it represents the fringe of the (mainly sub-littoral) Laminarian zone.

---

* The Constitution of the Intertidal Fauna and Flora of South Africa. Part 2. By T. A. Stephenson. With Plates XII–XIV and 13 text-figures. *Ann. Natal Mus.*, 10, Part 3 (Dec. 28, 1944).

The replacement of certain forms is interesting. Thus the polychæte *Gunnarea capensis* drives out *Patella cochlear* in places, and mussels replace limpets in others. Also algæ replace other algæ or limpets. The illustrations of the zoning, in many cases coloured, are very attractive and informing.

Such a survey as this can only be done by steady team-work, and the difficulties overcome are very large. Prof. Stephenson is to be congratulated on the large amount of valuable work accomplished, and it is hoped that it may continue on the same lines.

FORTHCOMING EVENTS

Saturday, July 7

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES (at the Rothamsted Experimental Station, Harpenden), at 9.30 a.m.—Fiftieth Annual Congress. Prof. W. G. Ogg: "Some Aspects of the Work at Rothamsted".

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (in the Physics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 2 p.m.—Discussion on "The Corrosion of Metals".

Tuesday, July 10

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Conversation and the Exhibition of Specimens.

Wednesday, July 11

GEOLOGICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Prof. W. W. Watts, F.R.S.: First William Smith Lecture.

Wednesday, July 11—Thursday, July 12

IRON AND STEEL INSTITUTE (at the Institution of Civil Engineers, Great George Street, London, S.W.1)—Annual General Meeting.

Wednesday, July 11

At 10.30 a.m. and 2.30 p.m.

Thursday, July 12

At 9.45 a.m.

Thursday, July 12

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1).—Dr. W. T. Astbury, F.R.S.: "The Structure of Biological Fibres and the Problem of Muscle" (Croonian Lecture).

Thursday, July 12—Friday, July 13

SOCIETY OF CHEMICAL INDUSTRY—Sixty-fourth Annual Meeting.

Thursday, July 12

(At the Chemical Society, Burlington House, Piccadilly, London, W.1), at 10.30 a.m.

Friday, July 13

(At the Royal Institution, Albemarle Street, Piccadilly, London, W.1), at 10.30 a.m.—Business; at 11.30 a.m.—Presidential Address; at 3 p.m.—Presentation of the Society's Medal to the Rt. Hon. Viscount Leverhulme, and Medallist's Address.

Friday, July 13

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion on "The Origin of the Solar System" (Speakers: Prof. W. H. McCrea, Dr. A. Hunter, Dr. R. A. Lyttleton and/or Mr. F. Hoyle).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

WOMAN ABSTRACTOR (Ref. F.4217.XA) with experience in scientific and technical abstracting, a GRADUATE PHYSICAL CHEMIST (Ref. F.4218.XA) with research experience in Rheology or Surface Chemistry; and a PHYSICAL CHEMIST (Ref. F.4219.XA) with Honours Degree and aptitude for research, by a Research Association—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2, quoting the appropriate Reference No. (July 12).

QUALIFIED DEVELOPMENT ENGINEER to take charge of Desig Testing and Development of range of Hydraulic Pumps (locatio Gloucestershire)—The Ministry of Labour and National Servic Appointments Department A.9, Room 5/17, Sardinia Street, King way, London, W.C.2, quoting C.2403.XA (July 13).

LECTURER IN THE DEPARTMENT OF PHYSICS—The Secretary, Th University, Edmund Street, Birmingham 3 (July 14).

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING in the Bradfo Technical College—The Director of Education, Town Hall, Bradfo (July 14)

DEPUTY BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Tow Hall, Great Yarmouth (July 16)

AGRICULTURAL CHEMIST, and a BIOLOGIST—Acting Director Agriculture, School of Agriculture, Houghall, Durham (July 18).

CIVIL ENGINEERS for service on a railway extension in Iraq—(Assistant Civil Engineer (Ref. E.1740.XA) capable of taking charg of setting out for railway construction, measuring up work, takin out quantities, and preparing certificates for payment; (*b*) Juni Civil Engineers (Ref. E.1705.XA) with good experience of instrume work for setting out earthworks for railway work, cross sectionin measurements, etc.—The Ministry of Labour and National Servic Appointments Department A.9, Room 5/17, Sardinia Street, King way, London, W.C.2, quoting the appropriate Reference No. (July 20

LECTURER IN INDUSTRIAL ADMINISTRATION and an ASSISTA LECTURER IN INDUSTRIAL ADMINISTRATION—The Registrar, Colleg of Technology, Manchester 1 (July 20).

LECTURER IN CHEMISTRY in the Constantine Technical College—The Director of Education, Education Offices, Middlesbrough (July 21

RESEARCH OFFICER FOR X-RAY CRYSTALLOGRAPHY, Division Industrial Chemistry, Council for Scientific and Industrial Researc Melbourne—The Secretary, Australian Scientific Research Liaiso Office, Australia House, Strand, London, W.C.2 (July 23).

ASSISTANT LECTURER IN THE DEPARTMENT OF ENGINEERING—Th Registrar, University College, Singleton Park, Swansea (July 30).

PROFESSOR OF GEOGRAPHY, and a LECTURER IN GEOGRAPHY, in th University of Ceylon—The Vice-Chancellor (Dr. W. Ivor Jennings, 23 Grange Road, Cambridge (July 31).

LECTURER IN FORENSIC MEDICINE AND TOXICOLOGY—The Secretar School of Medicine Committee, Westminster Hospital Medical School 17 Horseferry Road, London, S.W.1 (July 31).

SECRETARY—The Director, School of Oriental and African Studies University of London, London, W.C.1 (August 15).

PROFESSOR OF CHEMISTRY—The Secretary, Royal Technical College Glasgow (August 31).

LUCAS CHAIR IN THE PRINCIPLES OF ENGINEERING PRODUCTIO (applicants should have high qualifications in Engineering an experience in industry)—The Secretary, The University, Birmingham (September 1).

LECTURER IN SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (September 30).

ASSISTANT LECTURER, or LECTURER, IN THE DEPARTMENT OF GEOGRAPHY (with good qualifications in Geomorphology)—The Registrar University College, Southampton.

HEADMASTER, Grade III (Honours Graduate, with interest in Technical Education) of the Technical High School—The Director of Education, Education Offices, Library Street, Blackburn.

GRADUATE TEACHER OF GENERAL SCIENCE, especially Chemistry, in the Technical Institute and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-upon-Trent (endorsed 'T').

PRINCIPAL of the Cardiff Technical College—The Director of Education, City Hall, Cardiff.

TEACHER (full-time) OF MECHANICAL ENGINEERING SUBJECTS, in the Technical Institute and Junior Technical School—The Clerk to the Education Committee, Education Offices, Trafalgar Road, Great Yarmouth.

TEACHER (part-time, evening) IN PHYSIOLOGY—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1.

ASSISTANT MASTER TO TEACH ENGINEERING SCIENCE, PRACTICAL GEOMETRY AND MACHINE DRAWING in the Heaton Technical School—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 2.

ASSISTANT MASTER TO TEACH SCIENCE AND MATHEMATICS in the Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham.

ASSISTANT LECTURER IN AGRICULTURAL ECONOMICS—The Registrar, University College of Wales, Aberystwyth.

LECTURER IN CHEMISTRY, with qualifications in Organic Chemistry—The Registrar, University College, Exeter.

TEACHER OF ENGINEERING DRAWING, ENGINEERING SCIENCE, Practical Mathematics, Workshop Technology, Jig and Tool Drawing, and Design, to Ordinary National Certificate standard in the Redditch Technical School—Mr. G. Brodrick, Education Office, Church Green West, Redditch, Worcestershire.

SCIENCE AND NATIONAL DEFENCE

NOTHING emerges more clearly from the debate in the House of Lords on May 29 on the control of German war inventions and that on May 30 on the future of directed missiles than the imperative need for a national policy for defence. Without such a policy clearly formulated and rightly aligned with those of the other members of the United Nations organization, there can be no security or world order, or effective prosecution of reconstruction plans. Unless satisfactory answers are forthcoming to some of these difficult questions and an honest effort made to achieve adequate solutions, all our plans for building a world free from fear and want and squalor may fall to the ground. The world organization adumbrated by the United Nations Charter, the control of Germany, and national defence and international security are all interlocked. The allocation of resources, both of materials and of man-power, between the different purposes must be carefully balanced, or mankind may be plunged once more into an armament race and a world war from which there may be no recovery.

There can be no doubt as to the immense importance of the part which science has to play in this question of national defence and of the control of Germany, and scientific workers have no more urgent duty than that of addressing themselves to this problem. It is not a task to be undertaken, however, in isolation from the rest of the community. There must be the fullest and widest possible public understanding of what science and the scientific worker can—and can not—do in this matter. Hence it is of the utmost importance that the report of the committee of scientific men which, Lord Cherwell stated, the Government has appointed to advise on planning our methods for controlling German industry and to consider the whole question of the future of German scientific research, should receive the widest possible publicity.

The two debates were of service in emphasizing the futility of attempting to organize a system of collective security without some reference to developments in new technique and the means of watching and controlling them ; they equally emphasized the need for further attention to the formulation of policy. At present, as Lord Cherwell stated, the requirements of the three Services in regard to new weapons are co-ordinated by a fully representative inter-Services committee, and intensive work on longer-term projects is being co-ordinated by a special organization in which all those interested besides the users, technicians and scientific workers from both within and outside the Ministries are represented. What will happen, if and when the Ministry of Supply vanishes, Lord Cherwell could not predict, and it was clear from his speech that no decision has been taken upon the organization of the Services, the continuation of the Ministry of Defence and so on.

These are all questions that should stand above party politics, and on which it should be possible to formulate a policy and an organization which would command the support of every party. That point of view and the urgent need for clear thinking on these issues has been further illustrated, since the debate, in the seventh and final report of the Select Committee on National Expenditure for the session 1944–45. One of the main lessons of modern war, it is observed, has been the essential need for maintaining the closest contacts between all three Fighting Services and a fully co-ordinated control over their operations in the field. The necessary corollary to this is the establishment of similar contacts and controls in their supply services and in the basic research upon which these in their turn must rely. Attempts to solve the major problems of administration and government organization involved must lead to reconsideration of the present allocation of departmental responsibilities, and the Select Committee reports its conviction that these problems must be squarely faced and attacked with the least possible delay. It is one of the first questions to which the new Parliament should give its close attention.

The Select Committee's report does not so much indicate the lines on which a solution is to be found as adduce evidence of the dangers of neglect and of the soundness of its conclusion as to the urgency of the whole question. Methods of control and accounting suitable for ordinary administrative expenditure are not necessarily, it points out, those that lead to the most fruitful achievements in research. For that purpose, block grants should be sanctioned for specified periods of years ; and parliamentary control of this type of public expenditure may require the development of a new technique.

In addition, there are the further problems of securing the maintenance, both in industry and under government control, of active and fully skilled organizations, with the necessary tools and equipment, for the development of new results flowing from basic research, and for carrying out specific applied research and linking up these establishments, so that the fullest unity of purpose can be maintained between research, manufacture and operational requirements. It is of first importance that the permanent cadre of the armed forces should always have available during peace-time an adequate quantity of the most up-to-date weapons and stores that continuing research and development can provide, not merely for the purpose of training and for use in any war in which the country may become involved, but also because by field experience the fighting man can himself play an important part in the most effective development of war material. This experience should be shared with the Dominions, and the present system for co-ordinating research and design between Great Britain and the Dominions should be continued in peace-time and the Dominions invited to co-operate intimately at all stages.

Without going into details of examples of wasted expenditure, the Select Committee points out that, taken together, such examples show that, at least during the earlier years, the daily cost of the War was unnecessarily increased and the duration prolonged because research had for long been starved, no adequate steps taken to maintain in peace a nucl of skilled men which could be rapidly and efficien expanded for the purposes of war, and because t system of departmental responsibility was insu ciently flexible fully to meet the changed requi ments. Critical examination indicates weaknes inherent in the system and roughness in its machine rather than failures in the execution of allotted tas These weaknesses should, however, have been fo seen ; and now that they are fully recogniz immediate and vigorous action should be taken put them right.

Maintaining the view which it has consistent upheld, that national economy can be firmly bas only on the best outlay of the nation's resources, t Committee has no fears that, if research and develo ment are maintained at a high level and encourag by the right methods of control and co-ordinatio and if the terms of employment offered attract t best brains to the service of the State, the nation bill for the equipment and maintenance of its forc in a state of fighting efficiency will be dispropo tionately large. In the long run, uneconom restriction in research expenditure and failure evolve means of securing the closest contacts betwee the scientific worker, the manufacturer and t fighting man must inevitably lead to gross extrav gance and perhaps imperil the existence of the natio It must never be forgotten that owing to a par monious attitude to research and consequent unpr paredness, the first two or three years of the W were spent by scientific men and research workers i a strenuous attempt to make up for lost tim Recurrence of these difficulties can only be prevente by securing the technical initiative during the year of peace and welding this to the war potential.

But technical initiative—which the Committe defines as the ability to develop and maintain technique of maximum weapon-power and to evolv a policy of strategy accordingly—is only one factor i defence policy. Account must also be taken of man-power reserves and economic resources, and the extent to which they can be mobilized in an emergency. Even technical initiative involves having at the service of the State trained scientific men, inventors and manufacturers whose continuing preoccupation with the problems of warfare will render them the more capable of speedily producing antidotes to new and unsuspected enemy devices.

An adequate defence policy, however, involves more than the considerations covered in the Select Committee's report and the establishment of appropriate relations both between departments and between civil and military research. It means also the quantitative and qualitative study of the man-power position of the nation, and a decision on the question as to whether conscription or other form of national service is to be a permanent feature of the national organization. It means decisions as to the size of the armed forces as a whole, and the relative deployment of man-power between them. Moreover, as the War has taught us, it involves making service in the armed forces an attractive career to able and public-spirited youth.

Again, on the production side, besides those alitative aspects implicit in the observations of the lect Committee, there are quantitative considerans equally important. The quantitative requirents for minimum defence needs will be dictated rtly by the decision as to the size of the armed rces to be maintained, which itself will depend in n on the defence organization established in -operation with others of the United Nations. ch requirements will also be related to the needs reseen during the expansion period required to ise production to its war-time level. Nor can a fence policy in its production aspect pretend to be equate or complete which does not take full count of the shadow-factory principle or that of spersion. Further, certain industries such as synetic rubber, high octane fuel, light metals and alloy eels may require special measures to ensure that e production is always in keeping with war-time otential needs and that they are not so located as be unduly vulnerable to attack. When such prolems as shipbuilding, aircraft production, food stocks d production, with all the repercussions which their lation to a defence policy must have upon indusial location and reconstruction and the allocation f man-power are also considered, the imperative ecessity for clear thinking on defence and for keeping he issues so far as possible free from all party controersies should be obvious. Only so can the cost of a efence policy which provides the material security, without which social security is impossible, be kept within limits which will not hinder the execution of hose measures of social reform and reconstruction on which hopes are so widely fixed.

(To be continued)

JEWISH PHYSICIANS THROUGH HISTORY

The Jews and Medicine

Essays. By Prof. Harry Friedenwald. (Publications of the Institute of the History of Medicine, the Johns Hopkins University, First Series: Monographs, Vols. 2 and 3). Vol. 1. Pp. xxiv+390+9 plates. Vol. 2. Pp. ix+391–817+3 plates. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1944.) 2 vols., 50*s*. net.

THE history of the Jewish physician, his role in the development of medicine, science and general culture and his influence on the fate and history of Jewry have not infrequently been the subject of articles, addresses and small monographs. Most of these tend to degenerate into crowded catalogues of eminent medical men who happened to be Jewish by faith or race. The Jewish physician has always been the child of his own age, and though very often highly original and ingenious, was not a creator or exponent of 'Jewish medicine', and this may explain the shortcomings of some of the historical representations which we possess without invalidating the need for comprehensive biographical studies of Jewish medical and scientific men set against the Jewish and general cultural background of their period. Yet, there certainly is a 'Jewish medicine'—the medicine of the Bible and the Talmud, specifically Jewish in its blending of ritual and hygiene, legal casuistry and medical knowledge. Medicine here emerges as a by-product of the primarily juridical and ritual concerns of the Talmud, and is to a large measure derived from the medical sources and schools of the Greco-Roman culture enveloping Jewish life in Talmudic times in Palestine and elsewhere. Nevertheless it is full of original features which stand out in its best representation, the "Biblical-Talmudic Medicine", by Julius Preuss (1911), to which one example may be added, the original prescription of sweets for 'Bulmus', that is, ravenous hunger due to a hypoglycæmic condition.

The present work is a collection of essays published, since 1917, by H. Friedenwald, emeritus professor of ophthalmology in the University of Maryland. Without attempting a comprehensive history of the whole subject, its treatment in the form of essays enables the author to exhaust his particular problem, and thereby to avoid the mistakes of his predecessors. The love for his subject, documented by fifty years of skilful gathering and studying of a unique collection of pertinent manuscripts, incunabula and books, animates his thorough and scholarly representation, which brings out new points, facts and vistas. Thus his "Bibliography of Ancient Hebrew Medicine" (Essay VIII) adds to that of Preuss many new items from the seventeenth century down to 1942, and is better arranged than any previous classification. Perhaps such a bibliography might be extended to cover even a wider range, including the medical aspects of 'Jewish archæology' (in the sense of Samuel Krauss), Jewish folklore, medical occultism, etc.

In a religious community, medicine has to establish itself. "The best of physicians is fit for hell" is an old Jewish epigram, because physicians are over-confident in their craft and tend to commercialize their profession. According to the Great Rabbi Loew of Prague, 'hell' stands for the material world which the Kabbalah holds to be negation of real existence, that is, the spiritual; the physician as well as the naturalist who knows only the material world will end in hell, that is, in non-existence. But Jewish physicians such as Maimonides were keen naturalists, averse to magic and superstitious practices such as the use of charms, amulets, etc., and the Talmud found subtle and progressive justification for professional medicine as practised by many of its authorities, the Rabbis, which may be read in the author's essay (No. II) on "Judaism and the Medical Art". "The Ethics of the Practice of Medicine from the Jewish Point of View" (Essays III and IV) found remarkable expression in "Apologetic works of Jewish Physicians" (1588, 1631, 1679).

The paramount role of the Jews in the preservation and transmission of Greek and Arabic medicine to the Occident is further illustrated by manuscripts acquired by the author and described in detail, to which a bibliography of medical works in Hebrew is appended (Essays VIII–XI). In the pre-Arabic period (seventh to tenth century A.D.), Hebrew had been used as a literary medium by such writers as Asaph and Donnolo. With the growing need for Arabic and Latin literature felt by Jewish students and physicians, these works were translated into Hebrew. During the Renaissance, humanistic interests account for the use and description of Hebrew anatomical terms by Vesalius and plant-names by Thurneysser, and for a Hebrew translation of the Hippocratic Aphorisms (Gaiotius 1647; it may be pertinent to add that as late as 1847 such a translation was published in Britain in Young's "Israelitish Gleaner", p. 33). The historian will welcome the lists of Jewish writers in Arabic and of the principal Jewish medical translators and their translations into Hebrew which are appended.

The picture would not be complete without extensive reference to the ordeals and difficulties to which the Jewish medical and scientific men were exposed, and much of this can be found in the biographical essays, especially those dealing with the Marrano physicians, which form the main part of the work under review. What the Jewish medical student had to face in these times is vividly described in "The Jews and the Old Universities". At certain Jewish "Schools" (for example, in Paris and perhaps in Mantua) medicine was taught in Hebrew. These schools rivalled in the fourteenth century the University of Paris, and the medieval universities, which were ecclesiastical throughout Europe, took formal action against Jewish students, though not until after the fifteenth century, and even then degrees were conferred on Jews on special authorization from the Pope. Jews served as distinguished lecturers in Italian universities from the fifteenth century onwards, and at Padua no less than 230 Jews qualified between 1517 and 1721—though not without a remarkable run of artificial difficulties. No such tolerance was practised in Protestant countries (with the exception of Holland). The prominent part played by Jews in the history of Montpellier, which probably owes its foundation to Jewish scholars from Spain, is the subject of a separate essay in which sketches can be found of Prophatius, the Saportas, Nostradamus, Sanchez (the famous sceptic philosopher), and Jean Astruc. The latter (1684–1766), celebrated as the inaugurator of the Elohist-Yahwist theory of Bible criticism and critical defender of the theory of the American origin of syphilis, came from a Spanish-Jewish family, as Friedenwald proves with finality (the fact as such was known before; see, for example, A. Sack, "The Problem of Genealogy of Syphilis". Aerztliche Mitteil. aus. Baden, 1932, p. 304).

It is these Spanish-Jewish families of Marranos from which sprung many of the most brilliant scholars and medical men and which, therefore, form the main subject of Friedenwald's biographic and bibliographic studies. Marranos were Jews in Spain and Portugal who were forcibly converted to Christianity, and in many instances continued in secret to practise Jewish ceremonies and transmit the Jewish religion to their descendants. To all familiar with their history it is well known that apparent or real devotion to the Church and high favour enjoyed at the hand of Emperor or Pope is no proof against the Jewish origin of a scholar. This particularly applies to Andres a Laguna (1499–1563), so far only known as one of the greatest physicians of his time and quoted as such by Cervantes, who, as Friedenwald shows, gave in 1555 the *experimental* proof that the root of nightshade causes certain "vain phantasmagorias" such as are associated with witchcraft, a discovery which enabled Laguna to oppose the age-old views of witchcraft, before Wierus, who is commonly regarded as the first in this field. The setting of this discovery is of particular interest. It occurs in an annotation to Laguna's Spanish translation of the materia medica by Dioscorides in the section entitled "Solano". When municipal physician at Metz in 1545, Laguna, as he tells us, recovered in t hermitage of two wizards (one of whom had be burnt as a witch), a pot with an ointment "that seem to be composed of the very coldest and sopori herbs; which are the cicuta, the nightshade, t henbane and the mandragore". He used it on t wife of the executioner who suffered from intractab sleeplessness. She fell into a deep sleep from whi she was aroused with difficulty after thirty-six hou and related her pleasant sensations during slee including cohabitation and "many other stran things", which were ascribed to the "cold" quali of the ointment causing a "frigidity in the diabolic parts from which there comes a humour as cold ice". Laguna concludes that witches, though deser ing of punishment for making a pact with the dev in reality never leave—neither in spirit nor in body the spot where they fall asleep. The devil imparts h knowledge of the virtue of such *pharmaka* to th witches, etc. It is noteworthy that the mediev rabbis (Maimonides, Gersonides and others) neve believed in the reality of witchcraft, and Amatu Lusitanus as well as Montaigne (the son of a Marran mother) may have been influenced in their enlightene views towards witchcraft by Laguna.

Space does not permit detailed reference to th many other essays, which include complete historica surveys of the Jewish physicians in Italy, and of Spain Portugal and south-eastern France, with a complet list (and 67 pages of short biographies) of the Spanis and Portuguese physicians after the expulsion at th end of the fifteenth century, and many individua biographies (notably of Amatus Lusitanus, and hi work in the discovery of the venous valves, Mon talto, and the eminent physiologist Moritz Schif (1832–96).

Here, then, is the first comprehensive source book for the history of the Jewish physician, a work indispensable for the student of history in general, Jewish history, the history of medicine and science, and last but not least, for the philosophical observer of human tolerance and of obscurantism. This latter aspect may be illustrated by passages from the essay on Jewish physicians in Spain and Portugal (pp. 614, 618, 647): "During the Moorish supremacy the Jews were among the leaders in the schools of Cordova and Toledo. They enjoyed a period of development in which their studies in science, medicine and philosophy . . . and their poetic productions thrived in so marvelous a manner that it is still described as the Golden Period." . . . "In 1148 . . . the fanatical Almohades conquered the land and the Jews were forced to accept the Muslim faith, their wives and children were sold as slaves and their synagogues and schools were destroyed." In Christian Spain towards the end of the eleventh century, Alfonso VI said: "Jews furnish our vezirs, chancellors and most of our officers . . . and we cannot do without them". But in 1391 a tide of discrimination led to frightful massacres. In Seville the mob killed four thousand Jews, in Cordova two thousand corpses lay in heaps in the streets and in the wrecked synagogues. From Cordova the spirit of murder spread throughout Spain to Aragon, Catalonia, Barcelona and Gerona. These persecutions were the immediate forerunner of the Inquisition.

The work is beautifully illustrated and produced, under the auspices of the Institute of the History of Medicine of the Johns Hopkins University and its director, Henry E. Sigerist, who contributes a preface.

WALTER PAGEL.

CAUSE AND SENSATION IN PHILOSOPHY

roceedings of the Aristotelian Society

New Series, Vol. 44: Containing the Papers read before the Society during the Sixty-fifth Session, 1943–944. Pp. xxx+160. (London: Harrison and Sons, Ltd., 1944.) 25s. net.

THE nine papers in volume 44 of the *Proceedings of the Aristotelian Society* cover a wide range of ubjects, including logic, psychology, ethics, religion. Three are likely to be of special interest to scientific readers. Though the authors approach the subject n different ways and quite independently, they all attack the phenomenalist or positivist view of scientific knowledge. Mr. J. C. Gregory, writing on 'Causal Efficacy", argues that those who treat causation as nothing but regularity of succession ignore the universal background of all thinking, primitive or dvanced. The notion of activity or efficacy belongs to this background. Dr. J. O. Wisdom in an article on "The Descriptive Interpretation of Science" admits that, so far as it provides a maxim of caution against postulation of unnecessary entities, the descriptive interpretation is useful, but urges that t cannot possibly be taken as final. Experiments are made and experimental science exists only because of the expectation that things will behave in definite ways; an expectation which the descriptive view dismisses as groundless.

Prof. H. H. Price, in his presidential address "Touch and Organic Sensation", clinches the argument with admirable force and lucidity. He points out that phenomenalists and positivists, all those who take the descriptive view of science, the regularity view of causation, and treat matter as a logical construction, are visual philosophers. "Hume *looked* at his billiard balls. And all that he could see was that one moved whenever the other struck it. Indeed, in any causal transaction there is nothing else to be *seen* except the concomitance of two events. But the tactual conception of causation is quite different." Organic sensation, if we take it to be the genus of which tactual and muscular sensation are species, reveals a world different from that of visual experience. The difference is specially marked if visual experience is taken, as it so often is, to exclude peripheral vision or anything ill-defined. The first main difference is that organic sensation is better analysed in terms of feeling and content (I feel tired) than of act and datum (I see a cat). The second is that it provides unity or wholeness as well as voluminousness and interpenetration, qualities singularly lacking in sight. As to its different modes, tactual experience gives rise to the obstacular conception of matter and muscular experience to the activity conception of causation. These conceptions do not arise in the first place from inferences made by comparing sets of experiences, but are given as qualities of tactual and muscular sensation. Lastly, muscular activity combined with other forms of organic sense provide a basis for self-consciousness; what it feels like to be alive.

The reason why organic sensation has been neglected and purely visual philosophy so much favoured is that for purposes of theory it is convenient to take sight as the model or type sense. Its range, flexibility and precision make it a specially suitable medium for theoretical statements. Moreover, long before science existed human language had developed a visual bias in its terminology. The result is that any other sort of perceptual experience tends to be interpreted in visual terms, and often, as Prof. Price argues, misinterpreted.

A. D. RITCHIE.

AMINO-ACID CONSTITUENTS OF PROTEINS

The Amino Acid Composition of Proteins and Foods

Analytical Methods and Results. By Dr. Richard J. Block and Diana Bolling. Pp. xiv+396. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas; London: Baillière, Tindall and Cox, 1945.) 6.50 dollars.

AT a time when the world faces a food shortage for man and beast, the nutritive evaluation of protein foodstuffs is a matter of first importance. The relative values of the different proteins in nutrition are based upon their content of those special amino-acids which cannot be synthesized in the animal body and are indispensable for its growth and continued health. All these 'essential' amino-acids are not present in every protein. With a knowledge of the amino-acid composition of the various animal and vegetable proteins, it is possible to choose proteins so that they become mutually supplementary, and thus to ensure a diet that contains the qualitative and quantitative requirements of essential amino-acids.

Obviously the selection of proteins to form an adequate diet depends on accurate estimations of the amino-acid constituents. The analytical methods used in such estimations are scattered widely throughout the literature. It is difficult without much experience to assess the value of several differing methods employed in the estimation of the various amino-acids. Dr. Block and Miss Bolling have collected together analytical methods for the estimation of the essential amino-acids and also of those non-essential amino-acids which can be evaluated with some degree of accuracy. In this way it is possible to compare the content of a specific amino-acid in the same protein as determined by many different procedures.

Attention has been directed to the one great difficulty in any accurate determination of amino-acids in proteins, which is the loss, to a greater or less extent, of the amino-acids by the process of hydrolysis. The methods which have been employed to arrive at an estimate of losses during hydrolysis are discussed in some detail for each of the main groups of amino-acids.

The authors have wisely given the various analytical methods in detail, including not only those employed for determinations but also for separation of specific amino-acids from protein hydrolysates. At the end of each section on a group of amino-acids, they have listed with references the values obtained by different workers for several proteins. Their opinion as to 'best values' may not receive general approval, but it is valuable to have such an opinion based as it is on wide experience.

This book is not only a most timely but also a most welcome addition to the literature of the proteins. It is well indexed and documented with a valuable bibliography. British readers will envy the way in which the book has been produced, with its clear printing on good paper.

Some British Moths

By Norman Riley. (King Penguin Book.) Pp. ii+30+16 coloured plates. (Harmondsworth and New York: Penguin Books, Ltd., 1944.) 2s.

ALL moths are not clothes moths, nor do all caterpillars eat cabbages, as many laymen still believe. There is much ignorance to dispel, and at the same time a growing appetite for knowledge of wild life to satisfy. This attractively written and produced book should gain both these ends, opening up new fields of pleasure for the man whose garden and now lighted windows attract so many moths, or who takes his leisure in the countryside.

Writing simply but vividly, the author gives an account of the moth's life-history—the various tricks that protect it from its enemies, the marvels of its eyes and organs of touch and smell, how it finds its mate, etc.—that makes fascinating reading. Caterpillars, not merely objects of interest, are shown as living animals with their own problems of concealment and protection, feeding and final transformation.

The forty-six moths illustrated, most of which can easily be found or reared, are necessarily a small selection, but they represent most of the 'macro' families, and the family likenesses are usefully pointed out. Notes on when and where the moths occur and how they live are given. The coloured plates are from drawings by the eighteenth century naturalist Moses Harris, some of which are published for the first time. Their freshness and richness of colour and the life-like attitudes, with larva, pupa and food plant also depicted, make them attractive illustrations. One or two of the smaller figures are perhaps rather blurred for identification purposes.

The Distribution of the Birds of California

By Joseph Grinnell and Alden H. Miller. (Pacific Coast Avifauna, No. 27.) Pp. 608. (Berkeley, Calif.: Cooper Ornithological Club, 1944.) n.p.

THIS work was commenced by the late Joseph Grinnell in 1934, and before he died in 1939 he had completed about half the species. In 1940 Mr. Alden Miller undertook to finish the volume and, in addition, to revise the typescript already prepared.

Under each species there is a list of synonyms which apply to Californian birds. The information is arranged under three headings: status, geographical range and habitat. The first, in addition to stating whether the bird is common or local, has some remarks on migration. The paragraph dealing with the range of the species gives all the records of distribution over the whole area and any which refer to nesting or occurrences on migration. In every case the authority or reference is added to each record. The final paragraph describes the type of country occupied by the birds during the breeding and non-breeding season. At the end of the book there is a supplementary list of introduced birds and species of uncertain occurrences.

Hence this is solely a detailed record of the distribution of Californian birds, which must have taken an immense amount of labour to compile.

There is no summary or deductions to finish off the work, but at the end of the introduction Mr. Miller states that it is hoped to publish later information dealing with various aspects of Californian bird-life, such as the differentiation centres for races, intrusions of faunas from adjoining continental areas, and other problems. This will be a very valuable contribution, and we shall look forward to Mr. Miller's additional volume. There is on coloured plate and a number of useful maps showin the distribution of various races.

Garden Birds

By Phyllis Barclay-Smith. (King Penguin Book. Pp. ii+30+20 coloured plates. (Harmondswort and New York: Penguin Books, Ltd., 1945.) 2s

MANY persons who are not skilled ornithologist take a considerable interest in birds, particularly those that visit their gardens, and they feel th need for a concise, well-written, well-illustrated, inexpensive book to help them recognize their garde inhabitants and visitors. This want has been supplied by Miss Barclay-Smith. She writes of the differen types of gardens and the birds likely to be seen in them, of what can be done in the way of planting special trees and bushes to encourage birds, of the plants they like, about deterrent measures against cats, the provision of nesting boxes and how to make them, also the provision of nesting material, and lastly the necessity to supply food and water. Feeders are discussed and the food to be supplied, reference being made to the widespread idea that coco-nut may prove fatal to tits. She says, "it is open to doubt. It is, however, a good thing to spread the nut with lard occasionally to prevent it becoming too hard." The reviewer in pre-war days when coco-nuts were easily obtained always had two or three hung up for the benefit of the tits and never knew a bird any the worse. Miss Barclay-Smith goes on to give individual descriptions of some score of regular garden birds in Britain, her accounts being illustrated by twenty colour reproductions of plates from Gould's "Birds of Great Britain", which are ever vivid and fresh. F. P.

Faiths of Many Lands

By E. Royston Pike. Pp. viii+103. (London: Watts and Co., Ltd., 1945.) 8s. 6d. net.

THE world contains many great and interesting religions. To most of us in Great Britain the greater number are merely names. In this unusual little book they become realities, and we read not only of the religions and their founders, but also of the millions who practise these religions, and what effect they have on the lives of the believers. The style is vivid and direct, and certainly arouses interest in the subject.

It is meant for children, but I think it is more suitable for adolescents, or for those who know very little about the subject, and want a simple, interesting introduction to it. It will give many an inclination to go further and read yet more about the Buddhists, the Mohammedans, the Hindus, the Parsees and so forth. ENID BLYTON.

Recent Advances in Endocrinology

By Prof. A. T. Cameron. Fifth edition. Pp. vii+415. (London: J. and A. Churchill, Ltd., 1945.) 18s.

THE fifth edition of this book is well up to date. More clinical detail is given here than in previous editions, and this makes the whole more coherent and readable. Among the mass of added material may be found descriptions of the use of 'tagged' atoms in the investigation of thyroid metabolism and of the use of thiouracyl and thiourea in hyperthyroidism. There are some new illustrations and a comprehensive bibliography.

THERMAL HISTORY OF THE EARTH*

By DR. E. C. BULLARD, F.R.S.
University of Cambridge

Observed Temperatures

THE surface temperature of the earth is determined by the balance between the heat received om the sun and that lost to the atmosphere and by diation into outer space. It is close to the mean r temperature and usually slightly above it.

It has long been known that the temperature nderground is higher than this surface value and creases with depth. The rate of increase varies eatly even when volcanic districts are excluded. or example, in the lower part of the Reef-Nigel bore the Transvaal the gradient is 7·8° C./km., whereas a bore at Eakring near Nottingham it is 54° C./km. ven in a single bore it may vary greatly at different epths; for example, in the top 550 ft. of a bore at Holford, in Cheshire, Benfield[1] found a gradient of 1° C./km., while from 550 ft. to 1,300 ft. the gradient was only 10° C./km. A large part of these variations s due to the varying conductivity of the rocks; for example, the top part of the Holford hole is in marls of mean conductivity 0·0037 cal./cm. °C., whereas the ower part is in marl and rock salt of conductivity 0·0094. The heat flow calculated from the product of the gradient and the conductivity is nearly the same at ll depths in the hole. The variations in heat flow rom place to place are also usually smaller than the variations of temperature gradient.

There is a large body of temperature data, much of which has been taken with great care. Unfortunately, in the absence of information as to the conductivity of the rocks in which the gradients are measured, little use can be made of this abundant material. In the seventies and eighties of the last century a committee of the British Association measured the conductivities of a number of typical rocks. In 1935 a further committee was appointed to investigate the conductivities of specimens from borings where the temperature gradient is known. Thanks to the work of these committees, there are now a number of places in Great Britain[1,2], South Africa[3] and Persia where the heat flow is known. There is also a determination by Hotchkiss and Ingersoll from a mine in Michigan. The mean results are:

	cal./cm.^{2} sec.
Great Britain	1·0 × 10^{-6}
South Africa . ..	1·2 ,,
Michigan	1·0 ,,
Persia (provisional value)	1·3 ,,

The British values probably require to be increased by about 40 per cent to allow for the effects of the ice age. When the ice melted about ten thousand years ago, the surface temperature must have been raised by about 10° C., and the gradient near the surface will have been initially reversed. This irregularity will have gradually spread downwards and subsided, but after ten thousand years the gradient near the surface will still be less than its equilibrium value. It is probable that a detailed study of the variation of heat flow with depth in a suitable British bore hole about 3,000 ft. deep would give fairly definite information on climate in the last ten or twenty thousand years. The conditions for satisfactory results are stringent and are not at present satisfied by any bore.

There is surprisingly little difference in the mean heat flows in Britain, South Africa and Persia. In particular, the very low South African temperature gradients do not result from a low heat flow, but are entirely due to the conductivity of the Witwatersrand quartzites being high compared to that of the shales, limestones and marls in which most British temperatures have been measured. The difference in the observed gradients is thus due to economic rather than to geological causes; in England, holes are bored in search of coal, oil or water; in the Transvaal, in search of gold. A South African bore that passes through shales, such as that at Dubbeldevlei, has a temperature gradient similar to those found in England.

The main need at present in this branch of the subject is for more conductivity data, so that the conductivities of the rocks in the numerous bore holes in which reliable temperature measurements have been made can be estimated. Recent American work[4] has made it possible to do this for igneous rocks, and a few hundred more determinations on sedimentary rocks would probably make it possible to estimate the heat flow within 10–20 per cent at a large number of points. Results from the Alps and from other major mountain systems would be of particular interest.

Aside from possible regional variations there are local variations, sometimes reaching a factor of two, between the heat flows measured in individual holes in a single district. Part of these are due to geological structure, that is, to distortion of the lines of flow of heat by departures of the strata from horizontal planes. A salt dome provides an extreme example of this; the high conductivity of the salt relative to the surrounding rocks will cause heat to flow towards it from all sides and will thus increase the heat flow over the dome and decrease it at neighbouring points. Variations due to this cause and to topographic irregularities can be computed or determined from models, and it is desirable that a few cases be investigated in detail in order to determine how far such effects will account for the observed irregularities. Recent denudation and intrusion of salt masses may also cause variation of heat flow. Strong[5] has suggested that these causes have been important in Persia. Anderson[2] has pointed out that high values of the heat flow are observed near the system of tertiary dykes stretching from Mull to Durham. The extent of such disturbances, the magnitude of which it is difficult to estimate, will perhaps be clearer when the direct effects of structure and topography have been more closely investigated.

Source of Heat

Only about 20 per cent of the observed heat flow can be accounted for by the cooling of the earth from an originally molten state. Kelvin, reversing this argument, showed that an earth in which heat was not generated could not have been solid for more than about twenty million years, and still have a heat flow near the surface as large as at present. The remainder of the heat is presumably derived from the radioactive decay of radium, thorium and potassium. During the last thirty years, much work has been done on the amounts of the radioactive elements present in rocks. The accuracy of the early work has been questioned by Evans[6] and others in America. They have shown that some workers have used incorrect radium standards and that there are other incompletely elucidated sources of error. Unfortunately, the new American work deals only with American rocks, and in considering the world-wide distribution of radioactivity we have no alternative but to use the old results. In 1936 a comparison of all the existing data was made by Jeffreys[7]; this showed a fair degree of consistency and it is possible that many of the data are more accurate than is sometimes supposed. As a general rule, sediments and basic rocks are of low radioactivity compared with acidic rocks. There is a wide variation in the radioactivity of specimens from a single locality, and a variation in the mean from place to place. The distribution is markedly skew and care is necessary in the statistical treatment of the data. A detailed investigation of a number of specimens of granite from an area where the petrology is well known would be of great interest. As granite is much richer in radium than the surrounding sediments, the distribution of radioactivity through the rock might throw some new light on the controversy as to how far granite is formed by crystallization from the molten state and how far by migmatization of sediments.

---

* A discussion with this title was held at the Royal Astronomical Society on March 23, 1945. It was opened by the present writer. The principal speakers were Mr. M. W. Strong, Dr. E. M. Anderson, Dr. H. Jeffreys and Mr. G. M. Lees. This article surveys the main points of the discussion and gives some additional comment.

A cubic centimetre of average granite produces about 0·5 to 1·0 × 10^{-12} cal./sec. The mean heat flow from the earth is about $1{\cdot}2 \times 10^{-6}$ cal./cm.^{2} sec., of which about 20 per cent may be of non-radioactive origin. The remainder could be produced by 10–20 km. of granite. This result means that the deeper parts of the earth must be almost entirely free from radium, thorium and potassium. If they contained these elements in anything like the same proportions as the surface rocks, the heat would be carried upwards by convection currents and would be conducted to the surface through the solid crust. If the rocks, by some miracle, solidified and stopped the convection currents, the heat would accumulate until melting again took place and the currents restarted. The present value of the heat flow can thus only occur if radioactivity to the extent shown by surface granite is confined to a crust 20–30 km. in thickness. Joly has suggested that there may be alternating periods of melting and solidification, but it is difficult to justify such a hypothesis.

There is some evidence that there is little or no granite under the main ocean basins. If this is so, the radioactive heat generated there may be expected to be less than that generated under the continents. It would be of great interest to verify this by heat flow measurements made under the oceans. There are serious but not necessarily insuperable difficulties in such measurements. The lower radioactivity will cause the temperature at a given depth under the oceans to be less and the density greater than under the continents. Such density differences, occurring at depths where the rocks are hot and probably possess little rigidity against long continued stresses, may cause convection currents moving upwards under the continents and downwards under the oceans. The density variations associated with such convection currents may provide the explanation of widespread fields of gravity anomalies which would otherwise force us to assume that the earth possessed considerable strength to great depths. The surface stresses produced by them may also play an important part in crustal deformation.

The deepest bore so far drilled is about 15,000 ft. deep. Beneath that, temperatures cannot be direc measured. Reasonable estimates may be made the outer 30–40 km. by assuming a structure bas on seismological results. The main uncertainty is the vertical distribution of radioactivity. The resu indicate that the temperatures are insufficient melt the rocks anywhere in the crust[8]. This sugge that extensive melting of the crust is only likely occur in geosynclinal areas where the crust thickened, or in some other abnormal circumstanc

As the surface heat flow is largely derived fro the radioactivity of the crust, it can tell us litt about the temperature below the crust. Theoretic estimates are subject to great uncertainty, b calculations have been made on the distribution temperature to be expected in a globe of molten ro which solidifies and thereafter cools by conduction[9]. Conduction only affects the upper five or six hundr kilometres; at this depth a temperature of abo 3,000° C. is reached. Below this, the gradient is equ to the rate of increase of melting point with dept due to the increasing pressure; this is probab about 3° C./km. Such a gradient would give a ten perature of about 10,000° C. at the outer edge of th core. The gradient in the thoroughly molten metall core is unlikely to be more than a few tenths of degree per kilometre, and the temperature attaine at the centre will not be greatly in excess of 10,000° C a temperature much less than that in the interior a star and almost within the range of laborator experience.

THE NEW ORGANIC CHEMISTRY*

By Dr. D. H. HEY

DEVELOPMENTS in the theory and practice of organic chemistry during the past ten years have opened up a new and broader outlook on organic reactions in general. The reactions of classical organic chemistry, which in the main are concerned with reactions between two molecules or with reactions between an ion and a molecule, have been embraced within a comprehensive electronic theory, the main features of which were firmly established about fifteen years ago. To-day many examples are known of reactions which do not possess the characteristic features of the electronic processes generally referred to as 'electrophilic' or 'nucleophilic', and it is now necessary to consider a third type of reaction, namely, those between a molecule and either an atom or a free radical. Provision for this third type of reaction is obviously necessary, since it is possible to sever a covalent bond in one of two ways, resulting in heterolysis or homolysis, thus:

$$A:B \rightarrow A: + B \text{ (heterolysis)}$$
$$A:B \rightarrow A. + .B \text{ (homolysis)}$$

* Abbreviated from a lecture delivered before the Alembic Club, University of Oxford, on March 5.

The reactions of the free radical triphenylmethyl e well known, and physical chemists have for some nsiderable time recognized the existence of simple ee organic radicals of short life in many gaseous actions; but the triarylmethyls are highly specialed radicals with which few chemists make contact, nd the main and most familiar reactions of organic hemistry, such as are suitable for general laboratory nd industrial processes, are not gaseous reactions ut reactions in solution which take place within a omparatively narrow range of temperature. The evelopment of the theory of homolytic processes in solution is therefore generally recognized as an dvance of considerable importance.

Most text-books refer to the aliphatic hydrocarbons nd ethers as inert stable compounds, but it is now necessary to define more clearly what is meant by he word 'inert'. Such compounds are admittedly easonably inert towards typical anionoid and cationoid reagents, such as acids, alkalis, and the halogens, but this stability does not apply to all eagents. Further, the text-books state that when aliphatic acids or acid halides are mono-chlorinated, the chlorine atom invariably becomes attached to the carbon atom adjacent to the carboxyl group. This, however, is only true for chlorine *molecules*. If chlorine *atoms* are involved the halogen becomes attached to the carbon atoms some distance removed from the carboxyl group. Yet again, according to the text-books, a substituent group attached to an aromatic nucleus directs the entry of further substituent groups into specific positions in the molecule. Some groups direct to the *ortho* and *para* positions, while others direct predominantly to the *meta* positions. Such conditions, however, only hold when the substituting agent is of the anionoid or cationoid type. If the substituting agent is a free radical, the laws of aromatic substitution no longer hold and substitution takes place invariably at the *ortho* and *para* positions and in many cases at all three positions. Numerous further examples can be given which indicate to what extent the text-books of to-day require both supplementing and correcting.

The significance of the participation of free radicals of short life in reactions in solution was first brought to light as a result of the study of one or two little-known reactions which could not be accommodated within the accepted electronic theory. Gomberg and Bachmann[1] had shown in 1924 that, when benzene diazohydroxide was allowed to react with a neutral aromatic compound, the laws of aromatic substitution did not hold, and that whatever so-called directing group was present the product was always a mixture of the *ortho* and *para* isomerides, thus:

$$\mathrm{PhN:NOH} + R\mathrm{C_6H_5} \rightarrow o\text{- and } p\text{-}\mathrm{PhC_6H_4}R + \mathrm{N_2} + \mathrm{H_2O}$$

As a result of a study of this and a number of closely related reactions, it was concluded that free radicals were involved[2], and the fundamental properties of aryl radicals formed under these conditions were then established for the first time[3]. These may be summarized as follows:

(i) Reaction with aromatic compounds gives *ortho/para* substitution (or in some cases *ortho/meta/para* substitution):

$$\mathrm{Ph.} + R\mathrm{C_6H_5} \rightarrow o\text{- and } p\text{-}\mathrm{PhC_6H_4}R$$

(ii) Reaction with aliphatic hydrogen compounds involves removal of hydrogen:

$$\mathrm{Ph.} + R\mathrm{H} \rightarrow \mathrm{PhH}$$

(iii) Reaction with aliphatic halogen compounds involves removal of halogen:

$$\mathrm{Ph.} + R\mathrm{Hal} \rightarrow \mathrm{PhHal}$$

These results led to further work which established the important fact that, contrary to the views of earlier workers, acyl peroxides give rise on thermal decomposition to free radicals[3,4]. This observation provided a satisfactory explanation for the 'peroxide effect' for the abnormal addition of hydrogen bromide, mercaptans, and sodium bisulphite to ethylenic compounds, and led to the widespread use of benzoyl peroxide for the initiation of chain reactions in solution. Further, the use of benzoyl peroxide as a catalyst for addition polymerization falls into line with Staudinger's theory of polymerization; and the recognition of the part played by such peroxides as a source of free radicals has resulted in many fundamental advances in our knowledge of polymerization.

There are at least five different ways in which free radicals of short life can be generated in solution. These may be summarized as follows:

(i) Action of heat:

for example, $\mathrm{PbEt_4} \rightarrow \mathrm{Pb} + 4\mathrm{Et.}$

(ii) Action of light:

for example, $R\mathrm{CO}R' + h\nu \rightarrow R. + R'. + \mathrm{CO}$

(iii) Discharge of an ion at an electrode:

for example, $\mathrm{MeCOO^-} \rightarrow \mathrm{Me.} + \mathrm{CO_2} + e$

$(R_2\mathrm{MgBr_2})^{=} \rightarrow 2R. + \mathrm{MgBr_2} + 2e$

(iv) Irreversible disruption of a molecule with evolution of a stable gas:

for example, $\mathrm{PhN:N}X \rightarrow \mathrm{Ph.} + X. + \mathrm{N_2}$,

where X is OH, Cl or acyloxy.

$\mathrm{PhN:NCPh_3} \rightarrow \mathrm{Ph.} + \mathrm{Ph_3C.} + \mathrm{N_2}$

$\mathrm{(PhCOO)_2} \rightarrow \mathrm{Ph.} + \mathrm{PhCOO.} + \mathrm{CO_2}$

$\mathrm{(MeCOO)_2} \rightarrow \mathrm{Me.} + \mathrm{MeCOO.} + \mathrm{CO_2}$

(v) Reaction of Grignard reagents with a metallic halide:

for example, $R\mathrm{MgBr} + \mathrm{CoCl_2} \rightarrow R\mathrm{CoCl} + \mathrm{MgBrCl}$

$R\mathrm{CoCl} \rightarrow R. + \mathrm{CoCl}$

and $\mathrm{CoCl} + R'\,\mathrm{Br} \rightarrow R'. + \mathrm{CoClBr}$

With regard to the properties of free radicals in solution, it is important to recognize (*a*) that a free radical in solution will not necessarily behave in the same way as would the same free radical in the gaseous state, and (*b*) that the properties of free radicals, like the properties of molecules, depend primarily on their chemical composition and constitution. In general, a free radical in solution can act in one of three ways, thus:

(i) Dimerization:

$$2R. \rightarrow RR$$

(ii) Disproportionation:

$$2R. \rightarrow R{+}\mathrm{H} + R{-}\mathrm{H}$$

(iii) Reaction with the solvent:

Aliphatic solvent: $R. + R'\mathrm{H} \rightarrow R\mathrm{H}$

$R. + R'\mathrm{Cl} \rightarrow R\mathrm{Cl}$

Aromatic solvent: $R. + R'\mathrm{C_6H_5} \rightarrow o\text{- and } p\text{-}R'\mathrm{C_6H_4}R$

In many cases all three reactions may occur simultaneously, but the relative proportions in which the three types of reaction take place depend mainly on the nature of the radicals themselves and also, but to a much lesser extent, on their concentration.

The methyl radical, like the first member of most homologous series, behaves rather abnormally since it mainly reacts with the solvent. With ethyl, propyl and butyl radicals the disproportionation reaction becomes more prominent, but some reaction with the solvent also occurs. With the higher alkyl radicals, dimerization becomes the main reaction, and reaction with the solvent becomes negligible. In the cases of radicals with branched chains and hydroaromatic radicals, the main reaction is dimerization. With the benzyl radical, dimerization is again predominant but with longer side-chains attached to the aromatic nucleus, as for example in the β-phenylethyl radical, disproportionation is the main feature. With aryl radicals the predominant and often exclusive reaction is a reaction with the solvent, whether aliphatic or aromatic, and dimerization is very rarely encountered. The effect of concentration is generally to favour the dimerization reaction, as would be expected. When free radicals are formed by the discharge of ions at an electrode, the local concentration of radicals may become momentarily very high, and in these circumstances dimerization may be encountered with radicals, such as phenyl, which in solution normally show no tendency in this direction.

Many examples of interest could be quoted of the practical applications of reactions involving free radicals or atoms. The use of diazo and related reactions for effecting the union of nuclei has been extensively employed[5]. In the medicinal field may be mentioned the synthesis of 1 : 2 : 5 : 6-dibenzfluorene[6], the important tumour-inhibiting agent, the preparation of compounds in investigations on the constitution of cannabinol[7], and the synthesis of new spasmolytic agents in the pyridylquinoline series[8]. In the field of colouring matters the reactions for effecting the union of an aromatic nucleus with a pyridine nucleus have led to the preparation of tetrapyridylphthalocyanines[9], which, unlike the parent blue pigment, are bright green in colour and can give rise to water-soluble quaternary salts which show affinity for cotton and viscose fibres, thus providing dyestuffs of the phthalocyanine series.

The capacity of benzoyl peroxide to yield free radicals provides the basis for many chain reactions in solution which result in halogenation and carboxylation reactions of an unusual type. Kharasch has shown that in presence of benzoyl peroxide, sulphuryl chloride acts as a chlorinating agent for paraffins, aromatic side-chains and aliphatic acids[10]. These reactions proceed by means of chlorine atoms, and when this method is applied to the fatty acids or acid chlorides it is found that the carbon atoms some distance removed from the carboxyl group are preferentially chlorinated, as opposed to the normal process of α-chlorination[11]. In an analogous manner oxalyl chloride in presence of benzoyl peroxide can be used as a carboxylating agent for aliphatic and carbocyclic hydrocarbons[12]. Another reagent which is considered to give rise to a neutral halogen atom is N-bromosuccinimide, which brominates at the so-called 'allyl' position[13]. With this reagent *cyclo*hexene gives 3-bromo*cyclo*hexene, just as 3-chloro*cyclo*hexene is obtained from the reaction between benzene diazochloride and *cyclo*hexene and 3-phenyl*cyclo*hexene is obtained from benzoyl peroxide and *cyclo*hexene. A particularly useful application of this reagent is for the degradation of the side-chain in sterols and bile acids, which removes three carbon atoms in one stage, thus :

$$: CHCH_2CH_2CO_2Me \rightarrow : CHCH_3CH : CMe_2 \rightarrow$$
$$: CHCHBrCH : CMe_2 \rightarrow : C : CHCH : CMe_2 \rightarrow : CO$$

The application of this series of reactions to 3-hydroxycholenic acid has been used in a new synthesis of progesterone, the hormone of the corpus luteum.

The free radical derived by removal of bromi from anethole hydrobromide readily undergo dimerization with the formation of the dimeth ether of the valuable synthetic œstrogen hexœstrol[1 The free radical in this instance was prepared b means of the action of a Grignard reagent on anetho hydrobromide in presence of cobaltous chloride.

In the application of the chemistry of free radica to the subject of addition polymerization the resul have been particularly striking. The generall accepted theory of the mechanism of additio polymerization, put forward by Staudinger in 193 and since elaborated by others, involves the primar formation of an activated molecule, which the reacts with a second molecule to give an activate dimeride ; this in turn reacts successively wit further molecules in the same way until finally th active centres disappear, primarily by disproportiona tion or reaction with a solvent. The initial activate unit and the intermediate units in the building up o the polymer are free radicals. The acceptance o such a free radical mechanism necessarily implie that the polymers so formed should contain fragments of the catalyst, and, if polymerization is carried out in a solvent, fragments of the solvent molecules also. Further, compounds other than acyl peroxides, which are capable of giving rise to free radicals, should also be capable of initiating polysolvent molecules in the polymer.

The presence of fragments of the catalyst in the molecules of polymers is unmistakably revealed in a number of investigations in which substituted or 'marked' peroxides have been used, containing atoms or groups the presence of which can be readily confirmed by analysis. In the polymerization of styrene in the presence of 3 : 4 : 5-tribromobenzoyl peroxide, the resultant polymer contained 15 per cent bromine, which corresponds approximately to one tribromophenyl group for each polymer chain[15]. It has also been found that polystyrene prepared by polymerization with benzoyl peroxide always contains oxygen, and this has been shown to be due to the presence of benzoate groups, as would be expected from the presence of benzoate radicals. The polymerization of styrene is not accelerated by the presence of a nitrobenzoyl peroxide, and this is attributed to a direct reaction between the free radical and the nitro compound. It had already been established some years earlier that nitro compounds were among the most reactive aromatic compounds towards free radicals[3]. It has also been shown that if styrene is polymerized in presence of nitrobenzene the polystyrene formed contains nitro groups[16]. Nitrothiophene is even more reactive in this respect than nitrobenzene[17]. Other workers have shown that, when polymerization is effected in the presence of carbon tetrachloride, the resultant polymers contain chlorine[18]. These results illustrate the incorporation of fragments of the catalyst and of the solvent molecules in the polymer.

Numerous cases have been recorded of the initiation of addition polymerization by compounds other than acyl peroxides which can decompose to liberate free radicals. For example, polymerization can be effected by means of tetraphenylsuccinonitrile[19], benzeneazotriphenylmethane[20], benzene diazohydroxides[21] and nitrosoacylarylamines[22]. These investigations provide convincing evidence in support of the free-radical mechanism of polymerization and add considerably to our knowledge of the subject.

From the above examples it will be evident to hat extent reactions of the type under discussion ave now permeated many fields of organic chemistry. he obvious importance of these developments, both rom the theoretical and practical points of view, ndicates that the time is approaching when it will ecome necessary to reconsider the manner in which he subject of organic chemistry is presented to the tudent. In the past the teaching of organic chemistry as been founded to a very large extent on the almost niversal and invariable tetravalency of carbon. The ewer approach must embrace not only the reactions f the tetravalent carbon molecule but also those of he trivalent carbon radical. It is also pertinent to ecall that in the past the raw materials for the rganic chemical industry have been derived almost xclusively from coal, but at the present time raw materials are also provided in ever-increasing quantity from the by-products of the petroleum industry. These raw materials, primarily hydrocarbons of various types, are frequently compounds normally regarded as inert, but which are by no means so inert towards reagents which give rise to free radicals or atoms. It is therefore to reactions of this type that we must look in order to develop fully the new resources now placed at our disposal. For these reasons I have chosen to include such reactions, not, it is hoped, entirely without justification, under the title of "The New Organic Chemistry".

AN EXPERIMENTAL TREATMENT OF THE APICAL MERISTEM IN FERNS

By Prof. C. W. WARDLAW
University of Manchester

In *Dryopteris aristata* an attempt has been made to observe the effect of isolating the apical meristem from the adjacent lateral tissues, while maintaining continuity with the pith parenchyma below. The first step was to ascertain the practicability of the operation. The procedure involves an operation roughly comparable with 'ringing' in an older region of the shoot, in that the incipient vascular tissue is severed. The difficulty lies in the fact that the treatment has to be applied to a minute region—the meristem—the tissue of which is soft, delicate and readily injured. Thereafter it remained to be seen whether a meristem so treated would prove capable of further growth. The successful outcome of such an experiment seemed likely to throw light on (1) morphogenetic processes at the shoot apex; (2) translocation of nutrients to the shoot apex; that is, whether this takes place by way of the undifferentiated vascular tissue or by upward diffusion over the whole cross-sectional area of the shoot; (3) the factors influencing the differentiation of the vascular system; that is, whether the effective stimuli proceed basipetally from the apex or acropetally from the older pre-formed parts; and (4) the physiological dominance normally exercised by the shoot apex over lateral buds or bud-primordia.

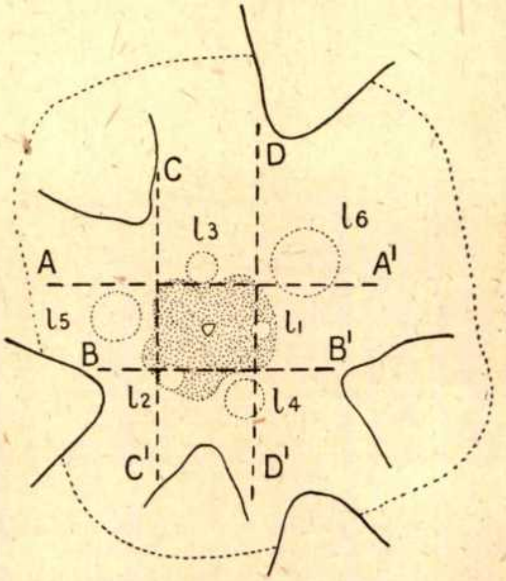

Fig. 1. Downward view of a small apex of *Dryopteris aristata* showing the apical meristem (stippled) and a succession of young leaf primordia (l_1, l_2, etc.). The system of vertical incisions by which the apical meristem is isolated from adjacent lateral tissues is indicated. (× 54.)

For these experiments the common broad-shield fern *Dryopteris aristata* was selected, plants of all sizes being obtainable in abundance. Previous experience has indicated that this species possesses very considerable vitality under experimental treatment.

An apex of *D. aristata*, as seen in longitudinal median section, may, for convenience, be considered to include three regions in basipetal sequence: (1) the apical meristem which consists of a single

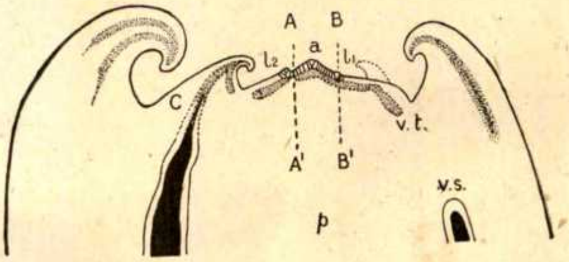

Fig. 2. Longitudinal median section of a large apex of *D. aristata* showing the isolation of the apical meristem by vertical incisions. (× 6.)

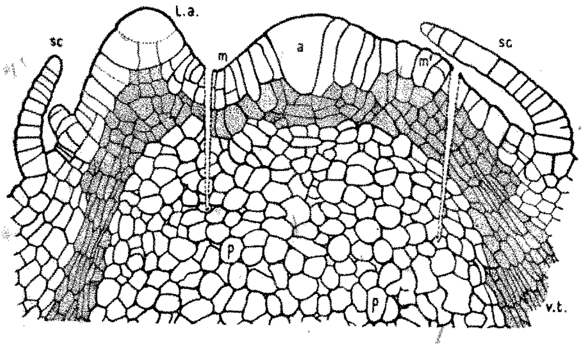

Fig. 3. LONGITUDINAL MEDIAN SECTION OF A SMALL APEX OF *D. aristata* SHOWING THE DETAILS OF AN ISOLATED MERISTEM. *m—m'*, APICAL MERISTEM, WITH LARGE APICAL CELL, *a*; *sc*, SCALE; *l.a.*, LEAF APEX; *v.t.*, VASCULAR TISSUE IN INITIAL PHASE OF DIFFERENTIATION; *p*, PITH. THE VERTICAL INCISIONS ARE SHOWN: THE ISOLATED MERISTEM IS CONTINUOUS WITH A THIN SHEET OF INCIPIENT VASCULAR TISSUE AND MEDULLARY PARENCHYMA. (× 100.)

layer of superficial cells, including the apical cell, of distinctive appearance and chemical reaction; (2) the region of initial differentiation, in which leaf primordia, buds and scales originate superficially from cells within or on the margin of the apical meristem and in which stele, cortex and pith can first be distinguished internally; and (3) the region of subsequent differentiation which merges downwards with the fully matured tissue systems. It should be noted that the incipient vascular tissue can be traced upwards to the region of its inception immediately below the apical meristem. Since the principal initial developments take place in region (2), it is there that experimental treatments must be applied.

The first step is to have unimpeded access to the apical meristem. At first sight this does not appear to be a very feasible undertaking. Indeed, because of the large number of rolled leaves and leaf primordia in the terminal bud and the dense investment of scales, the apices of ferns have not generally commended themselves as providing favourable materials for experimental investigations. Nevertheless, it is a fact of experience that there is little difficulty in removing the scales and leaf primordia from stout shoots of *D. aristata* or *D. filix-mas* and thereby laying bare the apical cone. These operations are carried out by means of small pointed scalpels and forceps, the material being observed under a binocul microscope. A downward view of a small shoot ap is illustrated diagrammatically in Fig. 1.

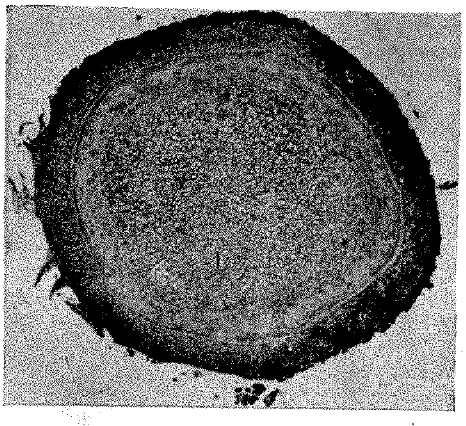

Fig. 4. SOLENOSTELE PRESENT IN THE SHORT AXIS DEVELOPED FROM AN ISOLATED APICAL MERISTEM. (× 20.) (*Photos* 4–7 *by E. Ashby.*)

To isolate the apical meristem from the adjace lateral tissues, and to sever the incipient vascul tissue, the following procedure was adopted. T terminal region of a stout shoot, trimmed to a leng of about 2–3 cm. and defoliated as already describe was observed under a binocular microscope at magnification of fifty times. By means of a smal thin-bladed scalpel four vertical cuts were made such a way as to isolate the apical meristem, on little square island of tissue, as indicated in Fig. In longitudinal section it will be seen that the isolate apical meristem, together with a thin layer incipient vascular tissue, is seated distally on plug of developing medullary parenchyma (Figs. and 3).

The system of incisions described above is obviousl only one of many that may be applied. For example the vertical cuts may be made on the margin of th apical meristem, within the margin, or outside it, s as to include one or more leaf primordia, and so on.

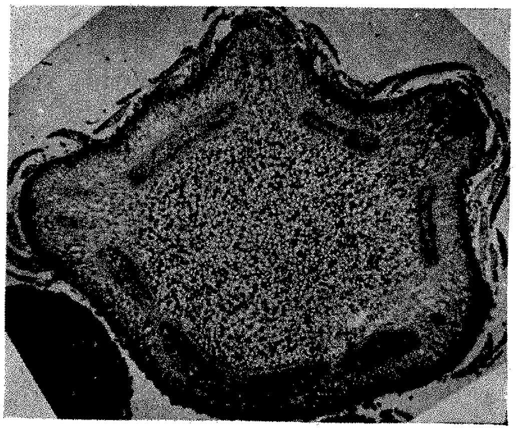

Fig. 5. DICTYOSTELE PRESENT IN THE TERMINAL FOLIAR REGION OF AN AXIS DEVELOPED FROM AN ISOLATED APICAL MERISTEM. (× 11.)

Again, leaf primordia of different ages may be isolated on separate plugs. I have found that isolating by four vertical cuts is simple and least damaging to the apical meristem, but other patterns, for example, by three cuts, are also possible. Radial cuts diverging from the margin of the apical meristem have also been made with interesting results. The procedure can be further varied by cutting more or less deeply into the tissue. In passing, it may be noted that the small size of the meristem precludes the use of a cork borer. The experimental and control plants were planted in moist peat in a cool greenhouse.

The isolated meristem is capable of growth. It develops into a short axis and in the course of four weeks may develop three or four new leaf primordia. In the course of three months, one specimen had developed a compact terminal bud in which fourteen leaf primordia were counted. In relation to the severance of the vascular tissue, the lower region of the axis consists entirely of medullary parenchyma. Higher up, a solenostele is present (Fig. 4). Still higher up, in the region of leaf development, the vascular system becomes dictyostelic (Fig. 5). The new leaves in the materials so far examined show normal

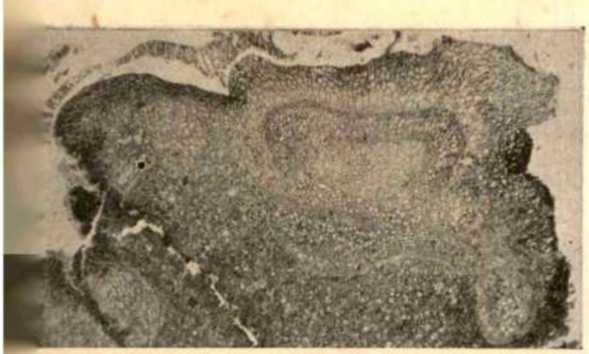

Fig. 6. TRANSVERSE SECTION OF A LATERAL SEGMENT OF AN INCISED SHOOT, SHOWING THE LARGE SOLENOSTELE OF A BUD CONJOINED WITH A MERISTELE OF THE PARENT SHOOT. (× 22.)

hyllotaxis and this is apparently in continuity with hat of the parent shoot. Whereas lateral buds evelop rapidly on the surrounding segments of the arent shoot, the new terminal axis is devoid of uds.

The lateral segments of the shoot are characterized y the development of very large axillary solenostelic uds (Fig. 6); they are thus in marked contrast to uds on the normal shoot, in which a small, nonmedullated protostele is present. Individual unifferentiated meristeles, isolated in lateral plugs as result of the system of incisions adopted, also show ome remarkable and hitherto undescribed developments, such, for example, as the development of olenostelic structure (Fig. 7).

Individual leaf primordia, isolated on plugs, undergo limited development only, and show a tendency o be thrust aside by more strongly growing axillary buds. In contrast to the normal development, in which the foliar conducting system consists of six to eight separate vascular strands disposed horseshoe fashion, the vascular system of an isolated leaf primordium is solenostelic.

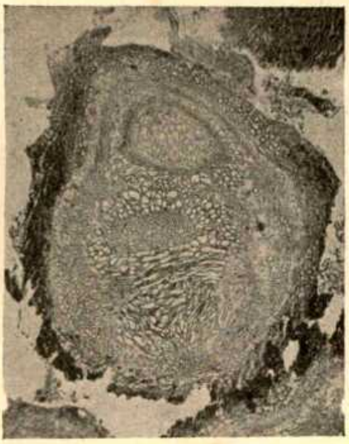

Fig. 7. TRANSVERSE SECTION OF A LATERAL SEGMENT OF AN INCISED SHOOT SHOWING THE SOLENOSTELE OF A BUD (TOP) CONJOINED WITH A MERISTELE WHICH HAS BECOME MEDULLATED (CENTRE); THE COMPACT MASS OF TRACHEIDES (BOTTOM) PERTAINS TO A SECOND MERISTELE OF THE PARENT SHOOT. (× 30.)

Thus, by using the technique described, many new and interesting observations have been made. These will be fully described and discussed elsewhere in due course. The answers to some of the questions raised in the opening paragraph are evident from the data submitted.

OBITUARIES

Dr. Stanley W. Kemp, F.R.S.

MARINE biology has suffered a heavy blow through the death on May 16 of Dr. Stanley Wells Kemp, and the loss of a wise and generous friend will be deeply felt by all who were associated with him. He rendered distinguished services to the Irish fisheries, the Zoological Survey of India, the Discovery Committee and the Marine Biological Association, and did much to stimulate marine research in Great Britain and overseas.

Kemp was born on June 14, 1882, the son of Stephen Kemp, and was educated at St. Paul's School and at Trinity College, Dublin. In 1903 he was appointed assistant naturalist in the Fisheries Branch of the Department of Agriculture and Technical Instruction of Ireland. In this post he gained a thorough practical knowledge of marine zoology, especially of the Caridea. He acquired valuable experience in deep-water investigations, and published several papers in the "Scientific Investigations" of the Department. This was followed by a period of fourteen years in India (1910–24), where he was first appointed senior assistant superintendent of the Zoological and Anthropological Section of the Indian Museum (which later became the Zoological Survey of India). Here he specialized in the study of Crustacea and began his "Notes on Decapoda in the Indian Museum", a valuable series of publications which continued until 1925. In 1916 he became first superintendent, under Dr. Annandale, of the Zoological Survey, and it is generally recognized that he and Annandale established an exceptionally high standard of zoological research in India. He accompanied various expeditions to study the fauna in different parts of India, including the expedition to the Abor country in 1911–12 (where he discovered the new genus *Typhloperipatus williamsoni*); and in 1922 he carried out the exploration of the Siju Caves in the Garo Hills. In 1916 he was elected a fellow of the Asiatic Society of Bengal, and in 1918 he brought out the important "Catalogue of Scientific Serial Publications in the Principal Libraries of Calcutta". While on leave in the following year, he took the degree of Sc.D. of Trinity College, Dublin, and visited the principal zoological centres in Europe with the view of establishing a marine biological station in the Andaman Islands.

Kemp was appointed director of research to the Discovery Committee in 1924, and it was under his far-sighted leadership that a well-equipped and many-sided organization was built up. The investigations were to include research on the general biology of whales (for purposes of the rational regulation of the whaling industry) and on other natural resources of the Falkland Islands Dependencies, and they involved an oceanographical survey of Antarctic waters, with attention to many subsidiary matters such as surveying and general collecting. This was an enterprise of a new kind which could be guided only to a limited extent by previous experience; but Kemp's remarkable capacity for organization in detail and his mastery of technical problems overcame all difficulties. Early in 1925 the Marine Biological Station was established at South Georgia, mainly for direct observations on whales. In the same year the *Discovery* (Scott's old ship, refitted for oceanographical research) sailed from England and shortly afterwards there followed the *William*

Scoresby, designed for whale-marking, experimental trawling, and general oceanography. The *Discovery II* which sailed in 1929 on the first of her five commissions was designed and equipped according to the requirements laid down by Kemp, and after the experience gained in voyages extending over nearly ten years, it would be difficult to devise any major improvements. The high standard he set in everything was also evident in the style of the Discovery Reports, of which the first volume appeared in 1929. Kemp sailed in the *Discovery* (1925–27) and *Discovery II* (1929–31) and at other times worked at his headquarters in London. It was under his direction that a new field of research was opened up which has led to much knowledge of whales and related subjects, and of the Southern Ocean in general, and which has in many ways advanced the science of oceanography.

In 1931, Kemp became a fellow of the Royal Society. For a time he was an honorary secretary to the Linnean Society, and in 1936 he received the Victoria Medal of the Royal Geographical Society. It was in 1936 also that he was appointed secretary to the Marine Biological Association and director of the Plymouth Laboratory. Here he found fresh scope for his administrative ability and capacity to stimulate research. He became the leading figure in marine biology, and much as he did to further the interests of the Laboratory, he was in contact also with the Discovery Committee, of which he remained a member, and kept in touch with his colleagues in India and Ireland. During the War his advisory activities were of great value, especially in the preparation of post-war investigations, and in this field his opinion carried much weight with the Colonial Fisheries Advisory Committee, the Development Commission, and the English and Scottish Fisheries Departments. He also sponsored investigations on seaweeds which arose from the war-time need for alginic acid.

In 1940 and 1941 the Plymouth Laboratory suffered heavily from enemy action, and though his own home and its contents were wrecked, it was largely through Kemp's personal initiative that the Laboratory was saved from complete destruction. He found safe accommodation for the valuable library, and instituted all possible repairs; and he had worked out comprehensive plans for the alteration and enlargement of the Laboratory in anticipation of peace-time requirements.

He married, in 1913, Agnes, daughter of the Rev. W. Spotswood Green, and had a daughter. In his home life Dr. Kemp enjoyed working with his hands, for he was a fine craftsman, and he found much pleasure as a collector of insect life. He was a man of modest nature with a keen sense of humour; his personality inspired great confidence and respect, and he had a shrewd understanding of human nature and a sense of values which was never led astray by the false or superficial. Those who sought his advice on professional or personal problems were never disappointed, for his judgment was always manifestly sound and sensible. It was an education to work under him, and he will be remembered with gratitude and affection by his many friends.

N. A. MACKINTOSH.

Prof. Eugène-Louis Bouvier

IT has recently become known in Britain that Prof. E.-L. Bouvier, for many years head of the department of articulate animals at the Musée National d'Histoire Naturelle de France, and later professor of entomol there, died near Paris on January 14, 1944. He w born on April 9, 1856, joined the Paris Museum 1883, and remained there for the remainder of active life, except during the years 1889–95, when was professor at the School of Pharmacy in Paris. 1902 he was elected to the Academy of Sciences, a became president in 1925. He received numer other distinctions both at home and abroad, and w a foreign member of the Linnean Society and t Zoological Society of London.

Bouvier's activities extended over an extraordi arily wide range of subjects. His earlier works inclu memoirs on Mollusca and Cetacea, and his well-kno monograph on *Peripatus*. Shortly after joining t Museum he became especially interested in t Decapod Crustacea, and his researches on this gro continued to the end of his life, Bouvier's last wor published in 1942, being devoted to the Corystoide His monograph on the Atyidæ is one of the bes known of his many studies on Crustacea. He al completed a monograph of the Pycnogonida.

While on a visit to Plymouth in 1913, he ma the interesting discovery (*Nature*, **91**, 633) of t transformation of the Phyllosome larva into t Puerulus stage of the common lobster.

Bouvier first became interested in the habits insects about 1900, and published studies on th psychology of certain Hymenoptera. In later year he devoted most of his time to entomology, and bui up an active department in this subject at th Museum. His general works on the subject includ "Habitude et Metamorphoses des Insectes", "L Communisme chez les Insectes", and "La vie psychiqu des Insectes", the latter, translated into English b Dr. L. O. Howard, being perhaps his best-know work in Great Britain. After retiring from th Museum, he continued to work on insects and during 1931–38 published six memoirs on the Saturnii moths.

Prof. Bouvier began his active career at a time when evolutionary doctrines were still being contested. He was a student of Edmond Perrier, and as a result of this influence his work was mainly directed to studies on the adaptive evolution of characters in various groups of animals and attempts to elucidate their phylogeny. He was a most enthusiastic research worker and knew how to communicate his interest to others. He became one of the best-known personalities in the scientific world of Paris, and his death removes one of the last links with the great French zoologists of the nineteenth century.

E. HINDLE.

WE regret to announce the following deaths:

Prof. E. Barclay-Smith, emeritus professor of anatomy in the University of London, on July 5, aged eighty-three.

Sir William Ellis, G.B.E., president during 1924–25 of the Iron and Steel Institute and during 1925–26 of the Institution of Civil Engineers, on July 4, aged eighty-four.

Dr. Robert E. Horton, hydraulic consultant to the Tennessee Valley Authority, and a member of the Institution of Civil Engineers, on April 22, aged sixty-nine.

Mr. A. G. Hastings White, C.B.E., honorary consulting librarian to the Royal Society, on July 8, aged eighty-one.

NEWS and VIEWS

Prof. Major Greenwood, F.R.S.

PROF. MAJOR GREENWOOD's retirement from the chair of epidemiology and vital statistics in the University of London marks the close of an epoch. Beginning his professional career as a physiologist at the London Hospital Medical College, the study of vital statistics early appealed to him. In addition to making advances in the mathematical study of the subject, he applied his knowledge as a touchstone to medical investigation. As statistician to the Lister Institute and, later, as chairman of the Statistical Committee of the Medical Research Council, his severe and wise scrutiny of data gave medical statistics a new meaning and elevated the standards of research into countless medical problems. During the War of 1914–18, he was in charge of the Medical Research Subsection of the Ministry of Munitions. "The Health of the Industrial Worker", written with Prof. Collis, records much of this work. The London School of Hygiene and Tropical Medicine was fortunate in securing his services in 1926, and he was made a fellow of the Royal Society in 1928. At the London School of Hygiene he soon gathered around him a band of workers trained in his special methods, while his teaching was highly valued by his students.

Prof. Greenwood's investigations with the late Prof. W. W. C. Topley wedded experimental epidemiology to statistical interpretation, and his book on "Epidemics and Crowd Diseases" further enhanced his reputation. The Royal Statistical Society made him its president, and he has enriched its proceedings by many medical and historical papers, which are models of English prose, adorned by wit and incisive epigram. It is not too much to say that Prof. Greenwood's work has revolutionized epidemiology and medical statistics, for he has ever been a searcher after truth and has shattered a multitude of false doctrines which impeded progress. It is satisfactory to know that his pupils—many of whom occupy influential positions—will carry on the torch which he has so successfully kindled. He vacates his chair not only with the regret of all who appreciate his great qualities as pioneer and teacher, but also assured that his work has added considerably to the sum of human knowledge.

Mr. M. A. C. Hinton, F.R.S.

MR. M. A. C. HINTON retired from his position as keeper of the Department of Zoology, British Museum (Natural History) on June 29. He has been associated with the Museum for many years, becoming a voluntary worker in 1910 and an assistant in the Mammal Section in 1921. He was promoted to deputy keeper in 1927 and took charge of the Zoology Department in 1936. His official work has, of necessity, involved most of the mammalian orders, but his principal contributions have been to the knowledge of the Rodentia. Numerous smaller papers, many of them with special reference to the species occurring in the Pleistocene of southern England, culminated in 1926 in the publication of the first volume of his monographic work on "Voles and Lemmings (Microtinæ) Living and Extinct".

But Mr. Hinton's interests have by no means been restricted to the purely taxonomic aspects of his subject. He has given considerable attention to the economic significance of rodents as enemies of man. His investigations into the musk rat menace in Britain entailed long, arduous periods in the field both in England and Germany. The order Cetacea has also attracted Mr. Hinton's attention. He prepared the report for the Interdepartmental Committee on Whaling from the papers left by Major Barrett Hamilton, who died while making investigations in South Georgia. This report is the foundation of much that was done eventually to ensure that whaling is carried out in a way least harmful to the stock from which the catches are made. It is hoped that Mr. Hinton, freed from the routine of an official post, will enjoy a long and active retirement, and that it will give him the opportunities he has long sought to concentrate on those zoological problems which, with his great knowledge and experience, he should do so much to elucidate.

Sir D'Arcy Thompson and Oxford

ON June 28, Sir D'Arcy Thompson, professor of natural history in the University of St. Andrews, was awarded the honorary degree of doctor of civil law by the University of Oxford. In presenting him to the vice-chancellor, the public orator (Mr. T. F. Higham) said that science and the classics each claim Sir D'Arcy as their own : as doctor of civil law, Sir D'Arcy will himself now be empowered to settle their rival claims. Mr. Higham also stressed the point that Sir D'Arcy has achieved the distinction, never more to be rivalled, of having been for no less than sixty years a professor. On the evening of the same day, Sir D'Arcy was the guest at a dinner party at which the announcement was made of a presentation volume of essays written in his honour, to be published very shortly by the Clarendon Press. Apart from contributors to the volume, there were present the vice-chancellor, Sir David Ross, Prof. E. S. Goodrich, Sir Henry Tizard, Prof. A. C. Dixon and Mr. Kenneth Sisam; and telegrams of congratulation received from many parts of the world were read.

Aeronautical Engineering at Bristol : Prof. A. R. Collar

MR. A. R. COLLAR has been appointed to the White chair of aeronautical engineering recently endowed in the University of Bristol by the Bristol Aeroplane Company ; he will take up his appointment on his release from national service. Mr. Collar was educated at Simon Langton School, Canterbury, and at Emmanuel College, Cambridge, taking honours in mathematics and physics ; he also took an honours degree in physics of the University of London. In 1929 he joined the staff of the Aerodynamics Department of the National Physical Laboratory, where he remained until the beginning of the War, since when he has been specially attached to the staff of the Royal Aircraft Establishment at Farnborough. At Teddington he carried out a wide range of aeronautical investigations, of which those affecting wind-tunnel design and aeroplane flutter problems are probably the most generally known. He is the author of many reports published by the Aeronautical Research Committee, and was for some time secretary of the Airscrew Panel and the Fluid Motion Panel of that Committee. Mr. Collar went to Farnborough to take charge of a special group of scientific men and engineers investigating aeroplane flutter and vibration problems. Working in close contact with aeroplane designing firms, this group has contributed notably to the safety of British aeroplanes.

New Stratosphere Aircraft

INFORMATION has just been released regarding a twin-engine stratosphere single-seater fighter, the Westland "Welkin", designed to deal with high-flying raiders. It is a mid-wing monoplane of 70 ft. span, weight 17,500 lb., single tail, and generally of conventional aerodynamic form. It is powered by two Rolls-Royce Merlin engines, of 1,650 h.p. each, fitted with two-stage two-speed superchargers sufficient to maintain the power at exceptionally great heights. Rotol four-bladed constant pitch airscrews are used, giving a speed of 385 miles per hour with a range of 1,500 miles. Its armament consists of four cannon, and the pressure cabin is fully armoured.

It is appropriate that this, the first stratosphere fighter to be adopted by the R.A.F. as a standard type, should have been designed and produced by the Westland Aircraft Co., which has specialized in the problem of high flying and was responsible, in pre-war years, for the equipment of the Mount Everest flying expedition. Many problems upon the design of pressure cabins have been solved in the experimental work on the "Welkin" that will be equally important to civil aviation. The automatic regulation of the air pressure is done by a valve developed by the firm, which is already being used on many other aircraft. Cabin heating and the avoiding of ice and mist formation on the windows is done by means of a 'heat sandwich'; warm air is pumped between two layers forming the pressure-resisting surface of the cabin, the same air circulating in the cabin and cockpit space. The temperature control has been found to be such that no special clothing was needed even at an outside temperature of – 78° F. At ordinary altitudes, either lower temperature than outside can be maintained or even cooled air can be circulated.

Geography in New Zealand

DURING recent years the study of geography has won recognition in most of the colleges of the University of New Zealand, and in 1944 a New Zealand Geographical Society was founded in Wellington with branches in the other main cities of the Dominion. This Society has now issued the first number of its journal under the title of the *New Zealand Geographer*, from its publishing office at Canterbury University College, where the idea of the Society was born. The journal, which is to appear twice a year, is to be concerned primarily, but not exclusively, with aspects of New Zealand, and is for home and overseas readers. The first number is devoted entirely to New Zealand topics and is written wholly by New Zealand contributors. Among several important articles is one by Mr. P. D. Sears on the regional variety of pasture growth in New Zealand. Since the country is primarily agricultural with chief interests in grazing, this study of the varying conditions of pasture growth is of much value. Another useful article is by Prof. C. A. Cotton on the geomorphic provinces in New Zealand. The *New Zealand Geographer* is well produced and promises to be a useful addition to geographical serials.

Bibliography of British Industry

A SELECT Bibliography on "British Industry and Commerce: Its History and Reconstruction" has been issued by the Sheffield City Libraries, to which Lord Riverdale contributes an introduction paying a deserved tribute to the services rendered to industry in the Sheffield district by the Science and Technology Library of the Sheffield City Libraries. The value of this service is well known to the research workers of the larger firms; but Lord Riverdale points out that Sheffield has in its Central Library one of the most valuable and effective research libraries on iron and steel in Great Britain. The bibliography is not limited to books and pamphlets but includes articles appearing in the more important reviews and scientific or technical periodicals during the last three years. Sections on Government and industry, effects of science and inventions on Society, statistical records, location and planning of industry, industrial research, research and education, British trade and commerce, finance and monetary reform and social security are included, but the bulk of the entries are arranged in the three subsections, history, pre-war organization and reconstruction, under the sectional heading British Industries and Public Services. The only important omission in the history subsection appears to be Sir John Clapham's recently published history of the Bank of England, but the absence of historical records of even large firms is noteworthy. The bibliography is admirably produced and printed; it faithfully reflects the trend of current thought in the fields covered and can be commended as an excellent basis for wider reading and study by those who wish to gain a clearer knowledge of the social and economic background in which scientific and technical research and industrial development proceed.

Azerbaijan Academy of Sciences

JACOB GIK, writing from Moscow, states that an Academy of Sciences has now been founded in Azerbaijan. Prior to its establishment, the Republic had a branch of the Moscow Academy, with twenty-two research institutes, etc. The new Academy has four main departments: agriculture, biology, geology and chemistry of oil, physics and technology of oil, together with a department of social sciences. The natural resources of Azerbaijan are now well known. Immense oilfields have been discovered and are now being developed. Geologists are investigating deposits of chromite, barytes and cobalt. The efforts of Russian men of science have made the province to a large extent independent of imported materials and enabled industry to carry on its work during the War without serious interruption. Physicists did particularly valuable work during the War. The Institute of Botany has published a comprehensive scientific work: "Agricultural Raw Materials of the Soviet Union". The Institute of Zoology is doing intensive work on problems connected with the effort to increase the yield of cotton, to rationalize the use of winter pasture lands, and to employ suitable local mineral fertilizers. A history of the literature of Azerbaijan from ancient times has just been published in two large volumes. The statutes of the Academy have been approved and fifteen well-known savants have been named as its first members.

Royal Society of Edinburgh

AT the ordinary meeting of the Royal Society of Edinburgh on July 2, Sir William Wright Smith, president, presented to the Society, on behalf of the subscribers, a bronze portrait head, by Benno Schotz, of Sir Edmund Whittaker, president of the Society during 1939–44. A copy will also be presented to Sir Edmund Whittaker. Mr. Stanley Cursiter presented to the Society a copy of his portrait of Sir

William Wright Smith. The Gunning Victoria Jubilee Prize (1940–44) was presented to Prof. H. W. Turnbull, regius professor of mathematics in the University of St. Andrews, and the Makdougall-Brisbane Prize (1942–44) jointly to Prof. Max Born, Tait professor of natural philosophy in the University of Edinburgh, and Dr. H. W. Peng. After the presentations Prof. Sydney Chapman, at the request of the Council and in terms of the Bruce-Preller Lecture Fund, addressed the Society on "The Earth's Magnetism".

Blackwell Prize and the Senior Hume Brown Prize in Scottish History

Two scientific workers, well known in the fields of scientific history and social technology, have just been awarded two unusual distinctions. Dr. Archibald Clow, of the Department of Chemistry of the University of Aberdeen, has been awarded the Blackwell Prize for a study of chemical contributions to industrial development. Dr. Clow and his wife, Nan L. Clow, have been carrying out research for several years on the contribution of chemistry to human welfare and development in the era of the industrial revolution, and the manuscript of the book in which they have embodied the results of their researches has been judged an outstanding contribution to history by the University of Edinburgh, which has awarded them the senior Hume Brown Prize in Scottish history. Both authors are graduates in arts and science of the University of Aberdeen, and Mrs. Clow particularly is well known for her contribution to the development of the scientific film society movement. Dr. Clow is a member of council of the Scientific Film Association. Dr. Clow is now working with the B.B.C., where he is taking charge of scientific broadcasts in a new programme to be produced in the early autumn.

Awards of the Veterinary Educational Trust

The Council of the Veterinary Educational Trust has awarded a Senior Wellcome Fellowship for Veterinary Research to Mr. Christopher W. Ottaway. After qualifying in December 1931, Mr. Ottaway was in veterinary practice for three years. He then entered the Anatomy Department, Royal Veterinary College, as a demonstrator and is now senior assistant in the Department. He has worked in the School of Veterinary Anatomy, Leipzig, and in the Department of Anatomy, Brno University Veterinary School, and has published a number of papers on anatomical problems concerned with domestic animals. His research work under the fellowship will be conducted at the Zoological Laboratories, University of Cambridge, and will be concerned with an investigation into the mechanics of the limbs of domestic animals and the factors which predispose to lameness and other diseased conditions.

The Council has also awarded a Wellcome Fellowship for Veterinary Research to Mr. Herbert Williams Smith. Mr. Williams Smith qualified in 1941 and has spent two years in private practice as an assistant. Since 1943 he has been an assistant veterinary investigation officer at the University College of North Wales, Bangor. He has contributed to the technical Press on the examination of milk samples for mastitis, and on the coagulase test for staphylococci. He has recently completed the examination of more than two hundred strains of staphylococci of animal origin with particular reference to determining criteria of pathogenicity. His research under the award will be concerned with the epidemiology of staphylococcal infections in animals, and will be conducted under Prof. G. S. Wilson at the London School of Hygiene and Tropical Medicine.

Conference on Automatic Controlling and Recording of Chemical and Other Processes

The Institution of Chemical Engineers, the Institute of Physics and the Chemical Engineering Group of the Society of Chemical Industry announce that the one-day joint conference on "Instruments for the Automatic Controlling and Recording of Chemical and Other Processes", which was postponed in September last, will take place at the Royal Institution, London, on October 19, 1945. The purpose of the conference is to promote the interchange of knowledge and experience between those using automatic controllers and recorders in different fields and to encourage collaboration between physicists and chemical engineers. The conference will be open without charge to all interested, whether members of the organizing bodies or not. Further particulars will be sent in September to those sending a request for them to the Organizing Secretary, Joint Conference, c/o the Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1. As there have been so many changes of address, those who previously asked for further particulars are asked to repeat their request.

Announcements

Sir Lawrence Bragg is lecturing in Paris at the Sorbonne, under the auspices of the British Council, on "X-Ray Analysis, Past, Present and Future", "The Strength of Metals", and "X-Ray Optics". The visit was arranged in response to a request from French men of science. These lectures conclude a series arranged by the British Council in France since February, but the Council is assisting the British Institute in Paris in making arrangements for future lecturers.

Mr. A. L. L. Baker has been appointed to the University chair of concrete technology tenable at Imperial College of Science and Technology. During the War he has been consultant to the War Office and Admiralty for marine works, and since March 1945 he has been employed in the Chief Scientific Adviser's Division of the Ministry of Works.

Dr. E. W. Smith has been elected president of the Institute of Fuel for the year ending October 1946; this will be his third year of office. Mr. J. F. Ronca, member of Council, has been elected honorary secretary of the Institute.

A British Medical Exhibition arranged by the British Council was opened at the Sao Jose Hospital in Lisbon last month by the Portuguese Under-Secretary for Education. The Exhibition includes books and instruments, and British medical films have been shown. The Portuguese Minister of Education sent a message paying tribute to the work of the British Council and its institutes in Portugal, and expressing the hope that more such exhibitions would be arranged.

Erratum.—The author of the communication "Naga, Naja, Naia or Naya ?" published in *Nature* of April 14, p. 457, is W. V. D. Pieris, not "Picris" as printed; throughout the note, the word 'Singhalese' should be 'Sinhalese'.

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Animal Learning and Evolution

Ever since the original enunciation by Baldwin[1] in 1896 of the theory of 'organic selection', the suggestion that local differences of habit (local 'traditions' as Elton[2] has termed them) may be the starting point for the evolution of new species of animals has been from time to time put forward in various forms. Such habit 'traditions', if entirely of a phenotypic nature, can of course only exist in animals in which there is some ability and opportunity for perpetuation of a particular type of behaviour or attachment to a particular environment or locality by means of associative conditioning, imprinting, or some other type of learning. Many peculiarities of behaviour which appear to be of this kind are known to naturalists; particularly to those who study such subjects as host selection of phytophagous and parasitic insects or the local variation in behaviour of birds (for example, song, nest-site, feeding habits, etc.). Many examples will be found in recent publications (refs. 3–8). That they may be very constant and persistent is suggested by the fact that, in a number of cases, highly characteristic and constant behaviour patterns of birds (such as song type), usually regarded as typical examples of specific characters, are now known to be, in part at least, transmitted from generation to generation by learning.

But while the idea that certain differences of this kind may be of evolutionary significance has proved attractive to various writers, it has been difficult, without invoking some form of Lamarckism, to visualize the mechanism whereby behavioural differences characteristic of local populations could become genetically fixed. It is true that the Sewall Wright effect might be operative in small populations; but recent criticism by Mather[9] makes the probable significance of the Sewall Wright effect appear less; and in any event Wright's theory, while it might provide for random change, would not of itself favour the genetical fixation of variation of the same kind and *in the same direction* as the pre-existing behavioural trend based on learning.

Huxley suggests (ref. 6, p. 524) that the organic selection principle might be expected to account for the replacement of non-heritable variations by 'mutations' (presumably merely on account of the increased adaptation to the niche thus conferred), and that "where the modifications are extensive the process of their replacement by mutations may closely simulate lamarckism". The object of the present communication is to suggest that recent developments in genetics and in the field of animal learning, particularly the concept of imprinting due to Lorenz and others (refs. in Thorpe[4]), make the principle at once more probable and easier to understand.

Mather[9] has pointed out that the kinds of character which are likely to distinguish races and species are polygenic, and that any small decrease in mating freedom between two populations, whether brought about by natural obstacles or by any other cause, will be sufficient to lessen the intensity of selection for good 'relational balance'. The result of this will be that when members of two such populations or strains cross, the offspring will be heterotic. Mather further brings forward evidence to show that heterotic individuals are often less fit than the parental types, and that the avoidance of heterosis is probably the most widespread stimulant of isolating devices. Such a system, once started, would be self-propagating and irreversible.

Suppose for the sake of argument that the initial basis of separation is a host-plant preference based on olfactory conditioning, or a 'locality imprinting' holding the animal to a restricted locality or environment[4], renewed afresh in each generation. Suppose also that this is strong enough and has continued long enough significantly to reduce the intensity of selection for relational balance. There will thus be a definite selective advantage for such new variants as favour more complete isolation. Among new germinal variants of equal magnitude, those which are of the same nature and direction as the phenotypic learned response already operating will, besides resulting in closer adaptation to the niche, be the most effective in furthering isolation, and will therefore be most strongly favoured by natural selection. Thus the learned or conditioned response of the animal to the environmental situation will, besides tending to reinforce and make effective slight topographical and geographical barriers, give momentum to, and set the direction for, the selective processes tending to bring about genotypic isolation. These selective processes will thus bring about the reinforcement and perhaps the eventual replacement of non-heritable modifications by genetic modifications, and will thus closely simulate a Lamarckian effect.

Inheritance of Melanism in Grey Squirrels

While shooting grey squirrels on the Duke of Bedford's estate at Woburn this spring, some specimens were obtained which throw light on the inheritance of melanism in this species (*Sciurus carolinensis* Gmelin). So far as can be discovered, there is nothing in the literature about this. Nelson[1] states that in some parts of America litters are found to contain a black young; but there is no information on the proportion of black to grey young, or on the colour of the parents.

A grey male and female were shot in March of this year at Woburn, and a litter of four young taken from the drey which they had been occupying. Of these, one was black. If, as seems likely, the adults shot were the parents, they would appear to have been heterozygotes, carrying the factor for melanism, and it may be assumed that a proportion of the young of the normal grey colour were also heterozygotes; thus melanism in this species seems to be recessive and unifactorial.

Another drey about half a mile away, in the same od, was found to contain a black female suckling single black young one.

Grey squirrels were first introduced into Woburn the late Duke of Bedford in 1890. The black ase was introduced later, but unfortunately ere is no record of the numbers involved, nor the locality from which the introduction was ade.

Melanic grey squirrels have been recorded from tario, the Alleghanies of Pennsylvania, New unswick, Michigan and Minnesota. They are stated occur locally, and to be confined to narrow limits. l these areas are included in the range of one subecies of *Sciurus carolinensis*, namely, *carolinensis ucotis* Gapper. It is possible that the melanism occurs ly in this sub-species; in which case the grey uirrel population of Great Britain includes the *ucotis* form. In Great Britain melanics are found so at Ashwell and Northchurch in Hertfordire[2].

The Continental red squirrel (*Sciurus vulgaris* L.) as a melanic form, which has been noted in large umbers in many parts of its range. Neither case as been analysed genetically.

A degree of variation is found in the melanic forms f both species. Melanic grey squirrels were found ith brown underparts, or with the hairs of the back pped with brown. One specimen had a streak of hite on the belly. The saturation of melanism ppears to be slight enough to be affected by variation f the rest of the gene complex.

Dr. E. B. Ford, of the Department of Zoology and omparative Anatomy, University of Oxford, and Ir. C. Elton, director of this Bureau, kindly gave dvice in this matter. The Duke of Bedford vas asked for details of the introductions into Woburn.

Heterokaryosis and the Mating-Type Factors in *Neurospora*

EXPERIMENTS on the production of heterokaryosis in *Neurospora* have disclosed a striking difference, in the relationship of mating type to heterokaryosis, between the homothallic species *N. tetrasperma* and the heterothallic species *N. Crassa*.

Hansen and Smith[1] have demonstrated the occurrence of heterokaryosis, that is, the presence of genetically different nuclei within individual cells of a mycelium, in Fungi Imperfecti. More recently this phenomenon has been discovered and investigated in *Neurospora*[2,3,4].

The heterothallic species *N. crassa* and *N. sitophila* each consist of two mating types which are separated at the time of ascospore formation. Single ascospore cultures only produce functional perithecia when brought into contact with cultures of the different mating type. *N. tetrasperma* also possesses two mating types; but in this species, the ascospore is bi-nucleate at its inception, one nucleus containing one of the mating-type or incompatibility factors, the second nucleus containing the opposite factor. A single ascospore culture is therefore heterokaryotic and self-fertile. Homokaryotic lines can be obtained, however, which contain only one or other of the mating-type factors and which do not form functional perithecia unless brought into contact with the different mating-type[5]. Dodge[3] found that, when a certain homokaryotic race of dwarf habit was combined with another race of poor vigour, a heterokaryon was produced showing much greater vegetative vigour than either of the parent races. This occurred whether the second race was of the same or different mating type from the original dwarf.

Beadle and Coonradt[4], working chiefly with mutants of *N. crassa* characterized by their inability to grow well in the absence of certain specific chemical compounds, obtained similar results. When two such deficient mutants were combined, they produced a heterokaryon which was able to grow at the normal rate in the absence of the substances required by the individual lines. There is thus a 'dominance' effect of the normal allele in one nucleus over the mutant allele in the other. These results, however, were obtained only when mutants of the same mating type were combined. Beadle and Coonradt suggest that the absence of this vegetative vigour when mutants of different mating type are combined is due to the tendency of such combinations to form perithecia rather than to grow in a vegetative manner.

Using mutants derived from the fluffy strain of *N. crassa*, I have made many such combinations, using mutants characterized by reduced vigour. In most instances, when the two components belong to the same mating type, a heterokaryon is produced approaching and often equalling the standard fluffy type in vigour. When the mutants are of different mating types, the two mycelia grow side by side or the more vigorous overgrows the other, without any evidence of heterokaryosis whatever. All attempts so far to obtain evidence of heterokaryosis involving nuclei of the two different mating types (which will be described elsewhere) have failed. It is not yet known whether the fusion of hyphæ containing such nuclei is inhibited or whether such fusion occurs but without the two types of nuclei becoming associated.

These results are taken to indicate that the association of nuclei of different mating types occurs at the time of sexual reproduction and not by fusion of vegetative hyphæ.

The difference between a homothallic species such as *N. tetrasperma* and a heterothallic species such as *N. crassa* appears to be that, in the former, nuclei containing the mating-type factors are attracted at all stages in their life-history, whereas in the latter they are repelled or kept apart until the time of sexual reproduction, as suggested by Dodge[6].

Bionomics of *Hylemyia cinerella* Fallen

A REVIEW of literature reveals that no account has been given on the bionomics of this species in Egypt. It is frequently met with during the spring and autumn; and the average person would be likely to take it for a small house-fly. It is a coprophagous species. It breeds in cow- and buffalo-dung and in human excrement, but the former is much preferred by the fly as a breeding medium. Experiments show that horse manure does not attract the female fly for oviposition. This fly was reared from human fæces by Howard[1]. Other coprophagous species of *Hylemyia* (*H. longicornis* and *H. strigosa*) have been reared from cow- and horse-dung[2].

The breeding season of *H. cinerella* is the spring (March and April) and the autumn (September). On March 4, 1944, three hundred third-stage larvæ were collected from buffalo-dung exposed in the open. These larvæ were transferred to the laboratory and each was placed in a tube with a small quantity of dung and the tube covered with muslin. The larvæ were left to metamorphose and were kept under observation. A few drops of water were added to the dung whenever it showed signs of becoming dry. It was found that the larvæ took three to four days to change to pupæ, and these were transformed to adults in about seven days. The temperature during metamorphosis was about 25° C.

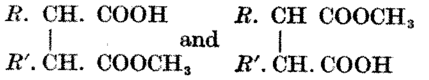
Inhibitory Action of Dialkyl Succinic Acid Derivatives on the Growth *in vitro* of Acid-fast Bacteria

THE elucidation, by Shriner and Adams[1], of the structures of the well-known leprocidal compounds, chaulmoogric and hydnocarpic acids, and the isolation, by Anderson and his co-workers[2], of tuberculostearic and phthioic acids, from the lipoid fraction of tubercle and other acid-fast bacilli, has stimulated synthesis of various branched-chain fatty acids by a number of workers. Of the large number of these acids synthesized by Adams *et al.*[3], the disubstituted acetic acids containing 16–18 carbon atoms were found to be most active against the leprosy bacillus *in vitro*. Adams's most active acid against the tubercle bacillus inhibited the growth of the latter in a dilution of 1/50,000[3]. Robinson and Birch[4] have synthesized a number of trisubstituted acetic acids having two long-chains and have found these acids to possess marked physiological activity resembling that of phthioic acid, producing cell reactions in animals as well as being strongly inhibitory of the growth of the tubercle bacillus *in vitro*.

The late Prof. T. J. Nolan suggested to one of us that roccellic acid, a product isolated from the lichen *Lecanora sordida*, having a branched structure, might be inhibitory of the growth of mycobacteria. This acid is a disubstituted succinic acid having the structure α-methyl-α′-*n*-dodecyl succinic acid[5]. It proved, however, to be only weakly inhibitory *in vitro* against *Myco. phlei* and *Myco. tuberculosis* (*bovis*). This was in agreement with the findings Adams relative to α-butyl-α′-*cyclo*hexyl ethyl succi acid. No significant increase in antibacterial activ was noted by us with other dialkylated succinic acd for example, α-methyl-α′-*n*-hexadecyl, α-α′-di-*n*-hep succinic acids.

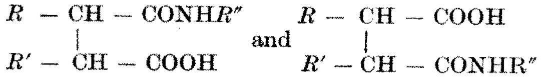
When, however, a methyl alcoholic solution of t anhydride of any of the above acids is neutraliz with dilute alkali, only one equivalent of alkali taken up and the neutral solution contains a mixtu of the isomeric monomethyl esters:



$$\begin{matrix} R.\,\mathrm{CH.\,COOH} \\ | \\ R'.\,\mathrm{CH.\,COOCH_3} \end{matrix} \quad \text{and} \quad \begin{matrix} R.\,\mathrm{CH\,COOCH_3} \\ | \\ R'.\,\mathrm{CH.\,COOH} \end{matrix}$$

A solution prepared in this way inhibits the growth the routine organisms, *Myco. phlei*, *Myco. smegmat* and *Myco. Rabinowitz* at a dilution of 1/20,00 1/40,000 of the monoester for six days (the duratio of the experiment) and *Myco. tuberculosis* (*bovis*) at dilution of 1/200,000–1/400,000 for 6–9 weeks whe certain succinic anhydrides are used. The employ ment of other alcohols in the production of the hal esters has shown that on the whole no improvemen in antibacterial effectiveness may be looked for i that direction.

The cloaking of one of the – COOH groupings wa also effected by preparing mixed monoanilides the type



$$\begin{matrix} R - \mathrm{CH} - \mathrm{CONH}R'' \\ | \\ R' - \mathrm{CH} - \mathrm{COOH} \end{matrix} \quad \text{and} \quad \begin{matrix} R - \mathrm{CH} - \mathrm{COOH} \\ | \\ R' - \mathrm{CH} - \mathrm{CONHR}'' \end{matrix}$$

where $R''\mathrm{NH_2}$ represents a wide variety of amino compounds, such as *p*-aminobenzene sulphonamide *p*-aminobenzoic ester, aniline, 2-aminothiazole, etc The inhibitory action of these compounds is of the same order as that of the half-esters but generally somewhat weaker.

All these active substances are strongly hæmolytic, bringing about the laking of washed human red blood cells in 30 minutes at a dilution of 1/50,000 on the average. Incorporating in the solution one eighth of its volume of human serum reduces the hæmolytic dilution to 1/2,000. Unfortunately, it was found that the antibacterial activity of the solution also was now weakened to a similar extent. Preliminary experiments indicate that the globulin fraction of the serum is responsible for the antagonism. It is generally assumed that an antibacterial substance which is strongly antagonized *in vitro* by serum or a tissue extract will prove ineffective *in vivo*. With a pathogen which grows so slowly as *Myco. tuberculosis*, it may, however, be possible to obtain a concentration of unadsorbed drug sufficient to retard at least the growth of the organism *in vivo*. As investigated so far, these drugs do not appear to be extremely toxic when injected intramuscularly into guinea pigs. Animal protection experiments are now in progress and the results will be published in due course.

Synthesis of other acids is proceeding, but present indications are that the molecular weight of the acid, or alternatively the total number of carbon atoms in the two substituents, must lie within a definite range to produce maximum tuberculocidal activity in the half-ester. Furthermore, with a definite molecular weight, maximum activity is reached when the two substituents are of equal magnitude.

Thus α-ethyl-α′-dodecyl succinic monomethyl ester inhibits *Myco. tuberculosis* (*bovis*) *in vitro* for six eks at 1/400,000, while the isomeric α-α'-di-*n*-heptyl d ester inhibits for three to four weeks at 1/800,000–,000,000 and for six weeks at 1/300,000. The ain used in these experiments was from the National llection of Type Cultures (No. 46) and was grown ordinary nutrient peptone broth.

These drugs inhibit the growth of *Staphylococcus reus* at 1/20,000 and *C. diphtheriæ* (*mitis*) at 40,000 *in vitro*. They do not affect the growth of *ct. Coli* or of *Aerobacter aerogenes* at 1/1,000.

We are indebted for fellowships to the Medical search Council of Ireland, which financed this vestigation.

'Fissibactericidal' Nature of Penicillin Action

WORK reported in several recent papers[1,2] has erified the bactericidal mode of action of penicillin n certain bacteria. The most important point rought out in these publications is that penicillin orks preferentially, or solely at low concentrations, n those bacteria in the growth phase or undergoing ctual fission.

Just as it was logical for one to search for anti-acterial substances produced by various micro-rganisms grown in the presence of bacteria, it seems logical that some of the moulds or other micro-organisms thus growing and competing with any bacteria present for the available food supply should finally become able to produce and secrete substances which are active in low concentration upon rapidly growing bacteria. The 'invading' bacteria would be of no immediate importance to such micro-organisms unless they were actively growing, since the latter would not have to share with them the food commonly available. This manner of action, which has been proved to exist *in vitro* for *S. aureus*, should it also be present in Nature, would offer a way of survival for the bacterial species in question, since any change in conditions which of itself would arrest active fission of the 'invading' bacteria would render them insusceptible to the antibacterial action of the penicillin-like secretion.

This above discussion must for the present be limited to penicillin, since the process has been proved for this substance only. The concept, however, is thought to be of more general interest and application and is pointed out for this reason.

It is felt that a new word is needed to describe the particular kind of bactericidal action discussed here, and typified by the action of penicillin on susceptible organisms (*S. aureus*). This word must mean an agent which kills bacteria only when they are growing or dividing, and in this sense, the term 'fissibactericide' is tentatively suggested. Since the experimental work to date has eliminated most of the other phases in the growth-cycle as ones during which the organism is most susceptible to the action of penicillin, the stem 'fissi-' has been chosen.

Additional work is being carried out which will extend observations on the *modus operandi* of fissibactericidal substances.

An Undialysable Pressor Principle in Organ Extracts

IN an earlier[1] communication the occurrence of an adrenaline-like pressor substance in ether extracts of various animal organs has been reported. The primary extracts were made with two volumes of alcohol. After evaporation of the alcohol from the filtrate and removal of fats and lipoids with ether, the clear aqueous phase was subjected to dialysis for forty-eight hours in 'Cellophane' bags against running water. The content in the bags after dialysis showed a strong pressor action on the cat in chloralose anæsthesia. On concentration and treatment with six volumes of alcohol, the pressor activity was found partly in the precipitate and partly in the filtrate. After this treatment the whole of the pressor activity became dialysable.

The two fractions, the alcohol-soluble and the alcohol-insoluble one, showed different properties. The former behaved in many respects like the adrenaline-like substance described earlier[1], whereas the latter was stable in alkali but destroyed by heating in an acid solution.

Purification work and analysis of the biological actions is in progress.

Losses of Nitrous Nitrogen from Soils on Desiccation

LOSSES of nitrite nitrogen from acid soils have been reported by a number of workers[1]. Recently, during the course of our studies on the losses of nitrogen from soils, we noticed that a part of the nitrous nitrogen disappeared when soils with a *p*H value higher than 7·0 were allowed to dry.

TABLE 1. EFFECT OF DESICCATION ON NITROUS NITROGEN OF THE SOIL.

Serial No.	Treatment of the soil	Mgm. nitrogen per 100 gm. soil		
		Am. 'N'	Nitrous 'N'	Nitric 'N'
1	Control	0·84	0·01	1·6
2	,,	0·84	0·01	1·6
3	With 5 mgm. nitrous 'N'	0·75	1·02	1·6
4	,, ,,	0·75	0·96	1·6

This observation was followed up to discover whether the observed disappearance of nitrous nitrogen took place due to one or the other of the following causes: (1) oxidation of nitrite nitrogen to nitrate; (2) reduction of nitrous nitrogen to ammonia; (3) assimilation of nitrous nitrogen by micro-organisms; (4) decomposition of nitrous nitrogen.

The results of experiments in this connexion showed that the disappearance of nitrous nitrogen was neither due to its oxidation or reduction, nor to its assimilation by micro-organisms, but that it was caused by its decomposition with the evolution of nitrous fumes. A desiccating soil containing 10 mgm. nitrous nitrogen per 100 gm. soil was actually found to smell of nitrogen peroxide.

Further experiments revealed that such losses took place only on desiccation and were not due to thermal decomposition of sodium nitrite.

TABLE 2. LOSSES OF NITROUS NITROGEN FROM SOILS KEPT AT 84° C. IN STOPPERED BOTTLES AND OPEN DISHES.

Serial No.	Treatment	Mgm. 'N' per 100 gm. soil	
		Nitrous 'N' in soil	Loss
1	Stoppered bottle	9·1	0·9
2	,, ,,	9·1	0·9
3	Open dishes	0·9	9·1
4	,, ,,	0·8	9·2

The nature of the soil was found to have a significant effect on such losses.

TABLE 3. LOSSES OF NITROUS NITROGEN ON DESICCATION FROM DIFFERENT SOILS.

Serial No.	Soil	Mgm. nitrous 'N' per 100 gm. soil		
		pH	Nitrous 'N' in soil	Loss
1	Sandy loam	8·7	2·4	7·6
2	,, ,,	8·7	2·6	7·4
3	Clay loam	8·7	1·1	8·9
4	,, ,,	8·7	1·2	8·8
5	Saline soil*	9·5	1·9	8·1
6	,, ,,	9·5	1·9	8·1
7	Alkali soil†	10·1	7·7	2·3
8	,, ,,	10·1	7·7	2·3

* Containing 1·02 per cent water-soluble salts (mostly chlorides, sulphate and carbonate of soda).

† Exchange complex nearly saturated with sodium ion.

Having established that nitrous nitrogen is actually lost from non-acid soils, experiments were conducted to study the reactions responsible for such losses. It was found that carbon dioxide and ammonia of the air, exchangeable hydrogen (which may be present in soils with pH higher than 7·0) and catalytic action of the soil were responsible for bringing about these losses. Of these the catalytic action of the soil seemed to be more important than others.

Detailed results are being published elsewhere.

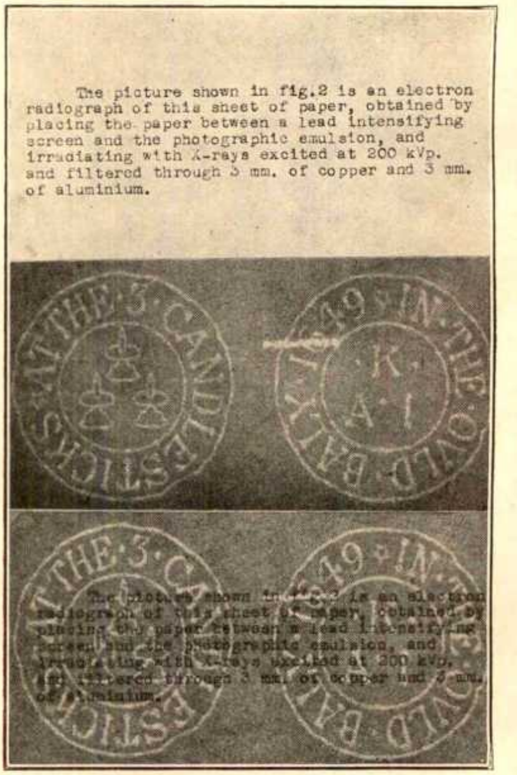
'Electron Radiography' using Seconda β-Radiation from Lead Intensifying Scree

IN order to obtain radiographs of thin, eas penetrated materials, X-rays generated at only few thousand volts (that is, Grenz-rays) have b used. This necessitates the use of a special Grenz- tube having a window transparent to the rays. numerous cases, however, excellent radiographs such materials can be obtained with the appara more commonly available in a radiographic depa ment, by employing the secondary β-radiation emitt under high-voltage X-ray excitation from the le intensifying screens which are frequently used high-voltage radiography.

The best procedure is to place the object to examined between a lead screen and a photograp emulsion in an X-ray cassette, as used in medi or industrial radiography. The lead screen may placed either between the emulsion and the X-r tube or behind the emulsion; but in either case t second lead screen normally used in radiograp should be dispensed with, and the object under exa ination should be in intimate contact with the phot graphic emulsion on one side and the lead screen the other. Single-coated film is preferable to doub coated as the electrons from the lead are almo completely absorbed by the film base and co sequently only affect one emulsion. The seco emulsion, therefore, only serves to increase the f on the film due to the direct action of the X-ray A 'contrasty' type of emulsion has been found



The picture shown in fig.2 is an electron radiograph of this sheet of paper, obtained by placing the paper between a lead intensifying screen and the photographic emulsion, and irradiating with X-rays excited at 200 kVp. and filtered through 3 mm. of copper and 3 mm. of aluminium.

Top: PHOTOGRAPH OF SHEET OF PAPER USING REFLECTED LIGHT SHOWING SURFACE PRINTING.

Middle: 'ELECTRON RADIOGRAPH' OF PAPER SHOWING WATERMARK AND ERASURE WITHOUT INTERFERENCE FROM PRINTING.

Bottom: TRANSMISSION PHOTOGRAPH WITH LIGHT; WATERMARK AND ERASURE PARTLY OBLITERATED BY PRINTING.

give the best results, and process films are particularly uitable. In order to reduce the relative effect of he direct action of the X-rays, it has been found desirable to use as penetrating a primary beam as possible, and hence to use a high kilovoltage across the X-ray tube. 150 kVp. can be employed, but better results are obtained at 200 kVp. and in both cases the softer components of the radiation should be filtered out. It is possible, however, that with very high voltages the improvement in contrast due to reduction in the general X-ray fog may be offset by a reduction in contrast through the increasing energy and decreasing absorption of the secondary β-radiation from the lead.

Suitable materials for radiography by this technique include paper, plastic materials such as cellulose fabrics, nylon, etc., and certain botanical subjects such as tree and plant leaves. The method is particularly sensitive to differences in thickness, and records of paper structure, watermarks, and in some cases erasures, may be obtained from printed paper without interference from the printing since many printing inks give no radiographic image. The technique is illustrated by the accompanying 'electron radiograph' of a piece of paper and comparison photographs using reflected and transmitted light.

In some cases the results may be complicated by the emission of β-rays from the material it is desired to radiograph. This is particularly liable to occur if the material contains elements of high atomic number. In some cases a 'positive' may be obtained instead of a 'negative', due to the β-emission from the material itself more than compensating for its absorption of electrons from the lead screen. In addition, baryta-coated papers may give a poor result on account of a faint but perceptible fluorescence excited in some samples of baryta by X-rays; this tends to fog the emulsion and greatly reduces the contrast of the electron radiograph.

Although the effect has only been studied with lead screens, there is no reason why other metals of high atomic number, such as silver, platinum or gold, should not give a similar result.

Accuracy of Atomic Co-ordinates Derived from Fourier Synthesis

In a paper, to appear in full elsewhere, I have investigated the accuracy of the atomic co-ordinates obtained from the three-dimensional Fourier syntheses of X-ray crystal structure analysis.

Representing the synthesis in the form:

$$D(x,y,z) = \frac{1}{V} \sum\sum\sum_{-HKL}^{+HKL} \mid F(h,k,l) \mid \cos\left[2\pi\left(h\frac{x}{a} + k\frac{y}{b} + l\frac{z}{c}\right) - \alpha(h,k,l)\right], \quad . \quad (1)$$

and neglecting errors of computation, two sources of inaccuracy occur: (*a*) experimental errors in the $|F|$ values; (*b*) errors due to (H,K,L) being finite.

Information as to the magnitude of the errors in the $|F|$ values has recently become available during a redetermination of the structure of dibenzyl by Jeffrey[1]. This structure was originally examined by Robertson[2], and a comparison of the two sets of experimentally determined $|F|$ values shows that the errors appear to be independent of the magnitude of the structure factors and to have a most probable value:

$$\Delta e = \pm 0{\cdot}6. \quad . \quad . \quad . \quad (2)$$

Examination of the shape of the atomic peaks derived from a number of Fourier syntheses shows that the radial density distribution can be closely represented by the function:

$$d(r) = Ae^{-pr^2} \quad . \quad . \quad . \quad (3)$$

where A depends on the atomic number of the particular atom and p appears to be fairly constant over a number of atoms from carbon to sulphur, a mean value being,

$$p = 4{\cdot}69. \quad . \quad . \quad . \quad (4)$$

A combined analytical-statistical analysis leads to the relation:

$$\varepsilon < 90{\cdot}8\,\Delta e/N\sqrt{V}(\lambda p)^{5/2}, \quad . \quad . \quad (5)$$

where ε is the most probable error in the co-ordinate, N is the atomic number of the particular atom, V is the volume of the unit cell in $A.^3$, and λ is the wave-length corresponding to the smallest spacings observed. Taking the values of Δe and p given in (2) and (4), and considering a carbon atom in a unit cell of volume

$$V = 583\ A.^3, \quad . \quad . \quad . \quad (6)$$

equation (5) leads, when all the information obtainable with copper $K\alpha$ radiation is used, to the value,

$$\varepsilon < 0{\cdot}0027\ A.$$

A formula is also given for the case in which errors are proportional to the order of their parent reflexions.

The problem of finite limits of summation is more complicated. For a simple system containing only two carbon atoms, the errors, calculated as upper limits, where ρ is the radius of the sphere containing the reciprocal points of all planes included in the summation, are:

ρ	ε(A.)
1·5	0·019
1·8	0·009
2·0	0·005

The polyatomic case cannot be given general expression since the atomic positions form a determined system and are not subject to statistical laws. In any *given* structure the errors can, however, be ascertained by the following procedure. Having calculated the structure factors from the final atomic co-ordinates, a synthesis is computed using these *calculated* values as coefficients. Any terms not included in the original synthesis with experimental coefficients are similarly omitted in this new synthesis. The co-ordinates derived will, in general, deviate slightly from those used in calculating the $|F|$ values; these deviations give the errors, with reversed signs, of the original co-ordinates. A trial on an actual structure[3] shows them to have a value of about

$$\varepsilon = \pm 0{\cdot}02\ A. \quad . \quad . \quad . \quad (7)$$

It is suggested that by applying these corrections to derived co-ordinates more accurate values of the latter may be obtained, having errors approximately those of experiment given by equation (5).

Finally, the value of p is related to the quantity B defined by Debye[4] and Waller[5] by means of the equation

$$\frac{1}{p} = a(B + c), \quad . \quad . \quad . \quad (8)$$

where a and c are constants. This relation enables the effect of thermal agitation to be examined.

A Colour Reaction in Yeast

AFTER being dried at 90° C., bakers' yeast pretreated with sodium fluoride assumes a more or less strong red colour, all according to the pH of the solution in which the yeast has been shaken. On the other hand, untreated yeast assumes a yellow colour after drying. With concentrated hydrochloric acid there is obtained from the red yeast a wine-red extract, which has a pronounced maximum at 4900 A. Fig. 1 shows the absorption spectrum of the extract in half concentrated hydrochloric acid.

After drying at 90° untreated yeast also gives a red extract with hydrochloric acid with the same absorption spectrum as is shown in Fig. 1. The intensity of the colour is, however, weaker.

Quantitative photometric determinations were carried out with solutions obtained by the drying and extraction of untreated yeast and also yeast pretreated with sodium fluoride at different pH's. The colour of the dried yeast was found to run parallel with the intensity of the colour of the extract. The maximal colour intensity was reached after a pretreatment of the yeast with sodium fluoride at pH 4.

Yeast dried over phosphorus pentoxide at room temperature gives a violet extract with hydrochloric acid. In this case, too, the same difference between untreated yeast and yeast treated with sodium fluoride was noticed. But the colour of the dried, treated yeast differs very little from the yellow colour of the untreated yeast. To get a red yeast, as to get a red extract, it is necessary to heat to 90°.

Further, fresh yeast gives a violet-coloured extract with hydrochloric acid without drying. In this case, too, treatment of the yeast with sodium fluoride increases the intensity of colour.

Quantitative photometric determinations were made with solutions which were obtained after the extraction of, on one hand, fresh untreated yeast, and, on the other, with yeast treated with sodium fluoride at different pH's. Maximal colour intensity was reached after treatment at pH 5. Fig. 2 shows the dependence on pH of the colour intensity of the violet and red solutions respectively, the former measured with filter S 52, the latter with S 50, of the Pulfrich Stufenphotometer.

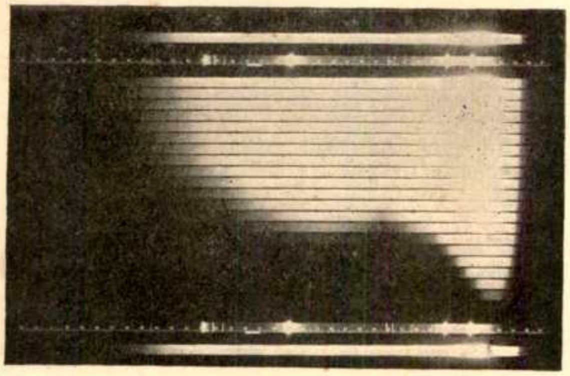

Fig. 1.

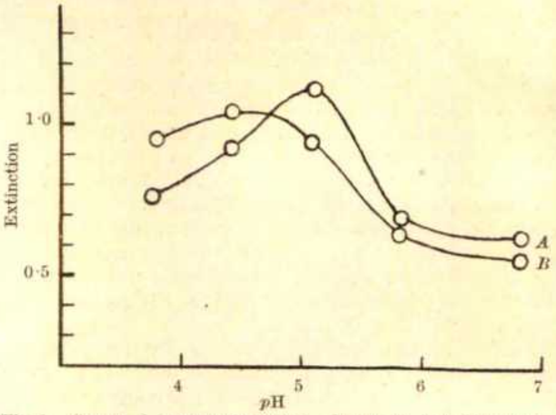

Fig. 2. CURVE A, VIOLET SOLUTION. CURVE B, RED SOLUTION.

When concentrated hydrochloric acid is added to bakers' yeast dried at room temperature, a violet extract with the same absorption maximum as the violet solution from fresh yeast is also obtained. After the dried yeast has been shaken in water for several hours, the colour intensity of the extract is reduced by subsequent treatment with hydrochloric acid. The cause may be either a washing-out of the colour-giving substance from the cell, or its partial transformation to a non-colour-producing substance. To discover the cause the washing-water will be examined.

Attempts to identify the red and violet colouring-matters formed were chiefly made spectrophotometrically, since attempts to isolate them have not hitherto been successful. With great probability they are condensation products between compounds containing an indole nucleus (tryptophane, skatole, indole) and aldehyde or ketone derivatives in the presence of a strong acid. The absorption spectra of such dye-stuffs have been examined by Bardachzi[1]. He observed that the spectrum could be broken up partly by heat-treatment, partly by the choice of indole nucleus source (pure tryptophane or proteins), and he assumed this to be due to the manner of binding of the tryptophane in proteins and their higher breakdown products. There is good agreement between his curves and mine. That the spectrum is broken 200 A. to the short-wave side in the case of the red extract in comparison with the violet one can thus be explained by Bardachzi's assumption.

In this reaction between tryptophane or its derivatives and carbohydrates in hydrochloric acid solution Jordan and Pryde[2] found a sensitive method of separating fructose from aldohexoses. Ketohexoses react at 40° in the course of 15 minutes, aldohexoses only at 80° in the same time. That fructose reacts specially sensitively is also known from other reactions, as in the Pettenkofer's reaction[3], and in the reaction between carbohydrates and phenols[4]. As I found, at 40°, the hydrochloric acid extract from yeast pretreated with sodium fluoride reaches full colour intensity in five minutes, that from untreated yeast, on the other hand, only reaches a weak colour

40° in 15 minutes, and a full colour intensity only 80° in the same time. Probably the promoting fect of sodium fluoride on the colour intensity is ue to accumulation of ketose in the yeast. Accord-g to the findings of Jordan and Pryde, it is more kely a question of a hexosemonophosphoric or hexosephosphoric acid accumulation than that of a riose.

In the case of yeast dried at room temperature, the rying process seems to play a similar part to the ddition of sodium fluoride.

Experiments seem to show that in the case of etoses the condensation with tryptophane commences at 90°, without the presence of a strong acid. herefore in the case of red dried yeast, too, the ssumption of ketose accumulation is a very probable xplanation.

That the carbohydrate metabolism is disturbed y sodium fluoride is well known. In the presence of dded substrate there is an accumulation of phosphoglyceric acid[5,6,7]. Without added substrate—as n my experiments—there is an accumulation of hexose monophosphoric acid in dried brewer's yeast[5], hexose diphosphoric acid in dried plasmolysed baker's yeast[8]. There seem to be no reports of possible accumulation products in the absence of added substrate in fresh bakers' yeast, for which reason the above-mentioned observations might afford an insight into related problems. On the basis of the observations of Jordan and Pryde, a sensitive colour-reaction for ketoses could be developed with the yeast substances as reagents. The quantitative determinations which have been made indicate that such a method would render it possible to follow, in a simple manner, even small variations in the quantity of ketoses in the yeast under varying conditions.

Halogenation in the Allyl Position

WE should like to make a few comments on the recent communication by W. A. Waters[1] in criticism of F. S. Spring[2] for stating that substitution in the allyl position of olefines is a new reaction attributable to Ziegler and his collaborators[3].

Although the reactions of halogen-containing substances with olefines to effect halo-substitution on allyl carbon atoms are of great interest, it seems to us that the most important reaction of allylic substitution is the *direct* halogenation of olefines at elevated temperatures discovered by Groll and others[4] in these Laboratories. Thus, for example, at temperatures of the order of 400° C., by an apparently homogeneous reaction, almost all the halogen in a 1 : 7 mixture of chlorine and propylene reacts readily by substitution to form allyl chloride. Bromine behaves similarly.

Waters conveys the impression that Farmer and his colleagues[5] were the first to show that the substitution into olefines in the α-methylene position was a reaction involving free radicals. In the reference to Farmer, cited by Waters, that author himself attributes the interpretation of the mechanisms of high temperature substitutive halogenation of olefines to two of the authors of this letter. It has been shown[6] that both addition and substitution occur under the experimental conditions principally, although not exclusively, by radical chain mechanisms, and that substitution is the dominant reaction at higher temperatures. Catalysis of the chain processes was achieved by the use of small amounts of tetra-ethyl lead, and, while under some conditions oxygen was a powerful suppressant of both reactions, under others a trace of oxygen acted as a powerful catalyst for the substitutive chlorination of propylene to form allyl chloride at temperatures as low as 272° C. In this connexion it may be mentioned that Ingold[7] states that peroxide catalysis (and hence by analogy oxygen catalysis) of a reaction is "compelling" evidence for a free radical mechanism. Such evidence is also accepted by Waters[8] as "conclusively" proving that such a process occurs. Of course, there is a wealth of experimental evidence for both acceleration and inhibition of radical reactions, from which may be cited Kharasch's oxygen- and peroxide-catalysed 'abnormal' addition of hydrogen bromide to unsymmetric olefines[9] and the quantitative photochemical 'anti-Markownikov' reaction involving such olefines and either hydrogen bromide or hydrogen sulphide[10].

As have others in the past[11], we wish to emphasize that the postulation[12] of free hydrogen atoms, produced by attack of organic radicals on molecules, as chain-carrying species in reactions is precarious, as the energetics of such reactions are generally entirely unfavourable.

As Spring noted in his report, due credit must be given to the chemists of the Shell Development Company of California for their original success in effecting the vapour-phase halogenation of olefines in the allyl position. While their evidence for the atomic mechanism of this process might have received mention, there can now be few chemists who would picture a homogeneous gas reaction of this type as anything other than a free radical process.

The mechanism of chlorine substitution in solution is, however, less well established, and in the past the N-halogeno imides, such as Ziegler's reagents, have often been represented as yielding either halogen cations (*a*), or molecular halogens (*b*) and not free halogen atoms (*c*):

(*a*) $R_2\text{N–Cl} \rightleftharpoons R_2\text{N}^- + \text{Cl}^+$ (unimolecular ionic reaction).

(*b*) $R_2\text{N–Cl} + \text{HCl} \rightleftharpoons R_2\text{N–H} + \text{Cl}_2$ (bimolecular reaction)

(*c*) $R_2\text{N–Cl} \rightleftharpoons R_2\text{N}\cdot + \cdot\text{Cl}$ (free radical reaction).

The prime reason for my comment in *Nature* of December 16, 1944, was to direct attention to this evidence for reaction by mechanism (*c*), in view of its theoretical significance in relation to the possible modes of covalent bond fission in solution, rather than to claim priority for proposing a mechanism for chlorination of olefines in the allyl position.

In establishing criteria for recognizing free radical reactions in solution, analogies with gas reactions are particularly valuable, though in commenting briefly on a particular reaction it is impossible to do more than cite recent relevant reviews (for example, my references 5 and 8).

Operators in Quantum Theory

IN his article on "Causality or Indeterminism?" in *Nature* of March 10, Prof. H. T. H. Piaggio refers to the restriction on quantum mechanical operators made by the condition that they be hypermaximal, and suggests that this conceals important requirements. In fact, the literature on the subject does not discuss the physical meaning of this requirement. Dirac, in his "Principles of Quantum Mechanics", substitutes the condition that "only those Hermitian operators that satisfy the expansion theorem represent observables": this is mathematically equivalent to hypermaximality, but also has no clear physical meaning.

The condition that an operator be Hermitian has the simple basis that the corresponding observable must have real values. It seems worth while to inquire what physical requirement on the operators can replace the above conditions. Now it can be shown that those, and only those, Hermitian operators are hypermaximal for which the corresponding Schrodinger equation

$$H\ \psi(t) = \frac{1}{i}\,\frac{d\psi}{dt}, \qquad . \quad . \quad . \quad . \quad (1)$$

with the initial condition $\psi(0) = \varphi$ has a solution for all positive and negative t and for every wave-function φ lying in the domain of the operator, H.

If, for example, we take the momentum operator for a line infinite in both directions—the operator $\frac{1}{i}\frac{d}{dx}$ operating on wave functions $\varphi(x)$ with

$$\int_{-\infty}^{\infty} |\ \varphi\ (x)\ |^2\, dx = 1,$$

then the equation (1) with the initial condition $\psi(x,0) = \varphi(x)$, has the solution $\psi(x,t) = \varphi(x+t)$ for all values of t.

If, on the other hand, we consider a half-infinite line, from 0 to ∞, the wave-function is $\varphi(x)$ with $0 \leqslant x < \infty$. As is easily seen, the operator $\frac{1}{i}\frac{d}{dx}$ operating on wave-functions in this half-infinite lin is Hermitian if, and only if, its domain is confine to wave-functions with $\varphi(0) = 0$. The equation (1 with initial conditions $\psi(x,0) = \varphi(x)$, has the solutio $\psi(x,t) = \varphi(x + t)$ for all negative t, where we tak $\varphi(x) = 0$ if $x < 0$; but for $t > 0$ the solution i formally $\varphi(x+t)$, which does not lie in the domain o the operator if $\varphi(t)$ is not zero. Hence the equation does not have a solution for all positive t. Thi corresponds to the obvious fact that a particle cannot move in a half-infinite strip with constan momentum for an infinitely long past and future.

The examples illustrate what happens in the genera case; since the equation (1) is the equation of a system for which the probability that the observabl corresponding to the operator H should have a give value, or should have a value lying in a given interva is constant, we can restate the condition in th following form:

A Hermitian operator is hypermaximal if, and only if, it is possible for a physical system to maintain a constant probability distribution of the observable corresponding to the operator for a time infinite i both directions.

This condition makes it fairly obvious why only hypermaximal operators obey the expansion theorem For that theorem to hold, the system must be capable of stationary states, that is, of states in which the probability distribution of the values of the observable is constant from $t = -\infty$ to $t = \infty$.

This approach to operator theory seems to link it more closely with the physical theory than does the theory of von Neumann and Stone. In a paper to appear in the *Quarterly Journal of Mathematics*, I have shown that it leads to a proof of the spectral theorem rather simpler than those of von Neumann and Stone, and also have proved the equivalence of the condition stated with hypermaximality.

Reform of the Patent Law in Britain

THE article on "Reform of the Patent Law in Britain"[1] criticizes my proposals for patent reform on the grounds that they would reduce the profitability of inventions to financial backers. I would maintain that my proposals would in general have no such effect. I have recommended that the Government should pay patentees rewards in proportion to the economic advantage arising from the application of their patents. Hence the wider these applications (be it by competitors of the patentees or by others) the higher the gains accruing to patentees. It is in fact an essential point of the proposed reform that it would not on the whole take away any of the financial stimulus for the exploitation of patents while leaving everyone free to use them. Even though a closer analysis might reveal cases in which the present form of patents would be somewhat more lucrative to patentees, these cases could be balanced by others in which the reverse would hold.

MICHAEL POLANYI.

University, Manchester.

---

[1] *Nature*, 155, 612 (1945).

THE point raised by Prof. Polanyi appears to be ased on a difference of opinion between him and he financial backers of inventors. He is of opinion hat the proposed reform "would not on the whole ake away any of the financial stimulus for the exploitation of patents while leaving everyone free to se them". On the other hand, however, the opinion f the financial backers, insofar as it has been ndicated during recent discussions of suggestions for he compulsory licensing of all patents, is that the nonopoly or *exclusive* licence obtained through the rant of a patent is generally necessary before the nancial arrangements for commercial exploitation f an invention become practicable. The small umber of patents that are voluntarily endorsed icences of right' under the existing arrangements hows that the opinion of inventors is, as a rule, in greement with that of their financial backers.

THE WRITER OF THE ARTICLE.

Strength of Glass and Duration of Stressing

IN the columns of *Nature* recently and in other laces there have appeared various discussions of the elation between the strength of glass and the duration of the stressing, frequently centring on the xperimental results of Mr. T. C. Baker reported in ny paper on the "Mechanical Properties of Glass"[1] n the form of a graph. There, breaking stress is plotted as ordinate against the logarithm of the time as abscissa. This is the way the scanty earlier results were plotted by other investigators.

To save the time of those who have been trying to fit equations to this curve, I may point out that if *reciprocal* of stress is plotted against logarithm of time a perfect straight line is obtained, for the glass specimen, the equation of which is

$$f \times \log_{10}(t/6) = 65{,}000,$$

where f is breaking stress in lb./in.^{2} and t is duration of steady load in microseconds.

If this curve can be extrapolated substantially the implications would be (*a*) at the long time end, the stress that can be supported for an infinitely long time is zero; (*b*) at the short time end, no finite stress can break these specimens if the duration is less than 6 microseconds.

The curve for porcelain rods shown in the same paper also reduces to a perfect straight line so far as the first five experimental points are concerned. The sixth point falls off the line, but the point was obtained by different apparatus in difficult circumstances and may perhaps be distinctly in error.

The physical meaning of implication (*b*), that glass and porcelain rods can stand an infinite load for a finite (but very short) time, is not at present clear. Perhaps the curve cannot be extrapolated too far that way, or perhaps the finite velocity of sound, or of crack propagation, comes in.

The outbreak of the War in the midst of Mr. Baker's researches, and other handicaps, have prevented any full account to the scientific Press of his work: the brief report in 1942 in my own paper above cited has caused much speculation, and Mr. Baker and I hope it may be possible to remedy the omission in the foreseeable future.

Avoidance of Obstacles by Bats

I HAVE read with great interest Mr. Pike's article on bats[1] and Squadron Leader A. K. McIntyre's letter[2] commenting on it. As the latter correctly states, it was Galambos and Griffin who were largely instrumental in proving that bats employ a supersonic form of acoustic 'radiolocation' when flying at night. They were not, however, the originators of this hypothesis, as they themselves state in their papers. This hypothesis was advanced by me as the result of a number of experiments performed in a set of rooms in King's College, Cambridge, the windows of which looked out on to the Cam. During the summer months, bats flew into these rooms in large numbers in the late evening and would remain there until dawn, flying round and round at will. They were unwitting collaborators in my experiments and continued to visit me without fear until the end of the long vacation. As a result of these visits I wrote an article in which I advanced the hypothesis that bats detect and avoid obstacles by hearing reflexions of high-pitched vocal sounds emitted during flight.[3]

This hypothesis has been substantiated in the three interesting papers by Galambos and Griffin.

The main problems of the flight of the bat apparently being solved, there are a number of minor ones to which attention may usefully be directed. I hope to deal with these later.

Archæological Exploration in South Africa

ON page 676 of *Nature* of June 2, 1945, reference is made to the South African laws which control the investigation of archæological sites and the collection and exportation of vertebrate fossils.

Control of archæological sites will meet with wide approval because their number is necessarily limited, and the evidence they can give is largely destroyed by excavation. But vertebrate fossils are in an entirely different position. The very important fossil faunas of the Karroo occur irregularly distributed over an area of some 100,000 square miles, a very considerable proportion of which is free from vegetation. They are, of course, not restricted to the surface, so that new specimens are constantly exposed by denudation. The total number exposed at this moment is certainly enormous, and it is certain that no conceivable amount of collecting can exhaust the field or even keep up with the exposure of new specimens.

A comparable case is that of the White River Bad Lands of South Dakota, where an area of some 2,000 square miles has been exploited for some fifty years by from one to a dozen parties each year and still yields enough to satisfy each visitor.

In fact, while the archæological restrictions are imposed for the protection of the evidence, that on fossil vertebrates is for the protection of the South African palæontologists, who do not appear to wish their colleagues to examine the new materials.

SCIENCE AND EDUCATION

THE Leeds Branch of the Association of Scientific Workers organized a highly successful and well-attended conference on "Science and Education" in the Philosophical Hall of the Leeds City Museum on the afternoon of June 9. Dr. W. T. Astbury was in the chair, and the opening address on "The Educational Policy of the Association of Scientific Workers" was given by Sir Robert Watson-Watt, immediate past president.

Sir Robert said that the only valid objective of a political system is a fuller life for each individual citizen, and that such intermediate objectives as a flourishing export market are merely means to that main objective. Since the export market is necessary to the fuller life, we want, in its interests as well as for other reasons, more technicians, more technology, more scientific workers and more science. But our greatest real need is for more culture, and he hoped that there will be no self-consciousness or shamefacedness in our campaign for culture as the greatest human necessity. It is perhaps fortunate, but only incidental, that more culture is essential to the attaining of more and better science and technology, and thus to a better export market.

To get better men of science their education must be changed, and it cannot be changed sufficiently without changing the education of every pupil and student in the country. In the education of the man of science we must include more principles and fewer facts, since the available facts are now tending to crowd the principles out of our courses. In the education of every student we must include more science and not less of the humanities. The disease which has ravaged our modern world is a disease of malnutrition. Diseases of malnutrition contain two major factors, defects of intake and defects of assimilation. The world's intake of scientific facts and technical products is not, as is sometimes foolishly suggested, excessive; but the intake has grossly outrun our assimilative activity, our appreciation of the inter-relation of the facts and our ability to apply the products beneficently. How can we improve assimilation? Sir Robert said he had been profoundly shocked to hear the Minister for Education in the late Government—a highly successful and progressive Minister for Education—tell a university audience that he "had not much use for mathematics and science" and that "the essential element in our education must continue to be the classics, because the classics tell us how people behave and how they will always behave". A very little store of the humanities of mathematics and science would have safeguarded Mr. Butler from this vicious extrapolation. Even if it had failed in that, it would have carried him to the natural conclusion of his thought process, which is that if people go on behaving as they have been doing, they will deprive themselves of any opportunity of behaving at all.

We must change our education: but where to begin, with the Minister or with the infant pupil? The former is an unpromising and laborious undertaking; the latter is a promising but slow-maturing one, which we must begin now. The quickest result will come from educating our educators, and that can only be done in the one place where true education can be given to true educators, the university.

Sir Robert then summarized briefly the salient points in the policy for education published by the Association of Scientific Workers: For the university, full access for all who can show a reasonable prospe of benefit, a doubled intake overall, a trebled intal for science, a trebled staff overall, capital expenditu of thirty million pounds in the next ten years, annu expenditure rising to the order of fifteen millio within five years, a national academic counci planned facilities for special schools avoiding alik complete monopoly and over-dispersal of the speci facilities. For the national institutes of technology which must be strengthened and extended to com parability with the best American models, integratio into the university structure without confusing th frontiers between the basic sciences and the highe technologies. For the technical colleges, an upwar levelling of status and facilities, and regional associa tion around the regional university as an intellectua and educational focus. For the young peoples colleges, a very great measure of autonomy to th student body, of self-government by the student fo the student. For the part-time student, in th sixteen to eighteen age-group, half of the forty-fou hour week devoted to daytime—and largely whol day—education, principally the education of the social conscience. For the post-primary pupil, leaving age of 15+ as a most urgent interim measure of 16+ at the earliest practicable epoch, an standardization at 16+ to facilitate uniformity o entry levels in the higher institutions. For the primary pupil, absorption of the common bases o scientific method through the pupils' own activity under the guidance of teachers who have themselves learned those bases for themselves. At all stages an intimate co-partnership with industry by the direct participation of those engaged in industry as members of council, as lecturers and as researchers.

Mr. H. Benfield, president of the Leeds Teachers Association, spoke on "The Place of Science in Primary Schools". Emphasizing the importance of basing education on the pupil's own activity and experience, on the encouragement of curiosity, the spirit of inquiry and wonder, he urged that nature study is the best initial approach to science, with progress from the collection of wild flowers through the primary school garden (left as nearly natural as possible) to the study of animals. The aquarium is a valuable means of overcoming urban limitations on this range of subjects. The pupil should learn to observe accurately, to record systematically—in pictorial form at first—and should not be launched in the primary stage on the formal study of a branch of science or of any organized science in detail.

Mr. E. J. Rose, Science Masters' Association, spoke on "The Teaching of Science in Secondary Schools", dealing with the age-group 12–16, with an advanced 50 per cent in the 16–18 group in present circumstances. Quoting the threefold justification for the place of science in a course the main aim of which is to provide an environment for the fullest development of the individual personality, the utilitarian or vocational, the disciplinary and the cultural, he said that while we stand high in literary and artistic performance, the highest glory of Western civilization is in its science. It is this glory, the glory of inquiry, which has to be revealed in the pupil's mind. Interpreting the syllabus for general science prepared by the Science Masters' Association, he re-emphasized the need for making full and continuous use of the pupil's own inventive capacity, the importance of the sentiment which grows up around any subject in the pupil's mind, the importance of adequate emonstration work, but not at the expense of ractical work by the student himself. He showed e need for improved facilities, for laboratory ssistants, for equipment of the kind now plentiful n Service training (episcopes, epidiascopes, projectors nd so on), for laboratories larger and more numerous han those of the present paper plans. Finally, he alled for direct contact between the science teacher and the worker on the frontiers of science, so that the eacher might absorb and re-transmit the spirit of cience.

Mr. J. Maddison, chairman of the Leeds Scientific Film Society, discussed "Teaching by means of the Scientific Film". He too stressed the practical problems of the film in education, the need for ample supplies of projectors and of copies of films, on a scale never yet reached in Great Britain. State production and use in war-time of instructional and informational films has shown the solution of these problems, by giving direct experience on a large scale in the economical making and utilization of such films, always a somewhat expensive business. That there are only 2,000 projectors, many unsuitable and many unserviceable, in British schools now is in part due to the apathy of teachers; that suitable films are scarce is due to the fact that there is no money in making educational films; the pre-war distribution of such films, costing £2,000 to make and £6–£7 per copy, was largely an aid to the sale of projectors.

The film must be a normal tool of teaching technique, and not a 'stunt' irruption into the classroom. It can be used as an incidental illustration to the lesson, as the central feature of the lesson, with other illustrative material grouped around it, or as an invaluable aid in the difficult task of keeping revision alive. The wider purposes of broadening the pupil's outlook, and awakening him to the excitement and drama of scientific outlook is better served by the use of the film in the main school hall, outside the classroom. The inadequate use of the film in adult education is largely governed by the economic factors common to juvenile and adult classrooms, but the commercial film theatre has its place in conveying the spirit and drama of science through the feature film, of which some dealing with continental scientific workers have been very good, though one dealing with a great English man of science was not a success. We need more projectors, more films, more skilled use and more research on the relation of the film to the learning process.

Prof. S. Brodetsky, ex-president of the Association of University Teachers, spoke on "Science and the University". He pointed out the close identity of the policies enunciated by the Association of University Teachers and the Association of Scientific Workers in relation to science and the universities, and suggested that closer co-operation based on this identity of view would be productive. He does not, however, believe that science in the university can stop short of the application stage; "Almost every branch of human activity is a branch of applied mathematics, if you look at it in the right way"; science produces the performance which is based on that application, and education in science cannot therefore be limited to principles. He commented on the relative failure to use the universities fully in the war effort; he regards the present tendency for "the Government to have its own private scientists" as an undesirable one.

There is a growing conviction that the university course is far too restricted and degrees far too specialized. A four-year course, apart from the specialized work, is desirable, and should be directed towards understanding of the safe and cultured life, the development of human thought, with application to the principles of government, economics, medical methods and so on. The thinker, the poet, the man of science, the politician, must not be separated and compartmented; they should learn together that there is no such thing as a branch of learning which is not exciting, fascinating and thrilling.

Dr. P. D. Ritchie, of the Association of Teachers in Technical Institutes, dealt with "Part-Time Technical Education". In the qualifications which the part-time student should bring to part-time education, he puts "a near mastery of written and spoken English" first, ability to transfer thought to symbolism second, ability to transfer to another language third, and knowledge of scientific method only fourth. He believes that we should aim at higher institutes equal to or better than the Massachusetts Institute of Technology and the Zurich Polytechnic, and that the great range of unrelated *ad hoc* courses offered at the technical college level should be brought to a closer relationship leading to a recognized label such as an external B.Tech. degree.

Prof. J. B. Speakman, head of the Textile Department of the University of Leeds, thinks that "The Education of the Technologist" must be carried out in an atmosphere of research, and thus essentially in the university and nowhere but in the university. Part-time education, he said, is a barbaric survival from the industrial revolution. The industries get their leaders largely from the elementary schools, and these leaders have never had contact with the research method which can transform crafts into applied sciences distinguished in their own right. Technological education must provide the men who would understand this process and would become the business men of the future.

Mr. C. V. Bellamy, member of the local executive of the Workers' Educational Association, spoke of the obstacles to success in the proper placing of "Science in Adult Education". The average worker fears science and is nervous of his own ability to tackle anything so complex; there is a shortage of competent tutors—"not every university lecturer or schoolmaster is successful with classes of people tired after a day's work"—and facilities are inadequate, equipment being frequently limited to that which can be borrowed and carried by the tutor himself.

Mr. C. B. Bradley, from a long experience in the administration of education, emphasized the importance of a realization—not always achieved—by members of local authorities that their responsibility to the pupil must take precedence over their responsibility to the ratepayer. "The scene of the struggle for educational progress has now shifted from Parliament to your own Local Authority." The school building of 1870–75, very frequently still in use, is deplorably unsuitable; in buildings and equipment alike it is impossible to exaggerate the bad conditions that prevail in hundreds of elementary schools still in being in all parts of Britain.

The Leeds Branch of the Association of Scientific Workers hopes that in a month or two it may hold a second conference, which will discuss the specific action that should be based on the very comprehensive and stimulating survey of the whole field which was achieved in this first conference.

ROBERT WATSON-WATT.

ESTIMATION OF MULTIPLE CORRELATION BY MEANS OF STEREOGRAPHIC PROJECTION

By G. F. K. NAYLOR

IN practice, the industrial psychologist is frequently faced with the situation in which he has to choose, from a trial test battery of say ten or more tests, those which will prove most effective in the selection of personnel according to some given criterion. He must then seek for answers to the following questions: (*a*) What is the individual validity of each test as judged by the criterion? (*b*) What combination of tests will give the best basis for prediction according to the criterion? (*c*) What will be the predictive value of such a combination? (*d*) How few tests may be used to obtain a validity coefficient the value of which does not depart appreciably from the theoretically best figure? (*e*) In what simple proportions must the scores of the chosen tests be weighted to obtain a close approximation to the best value of the joint validity coefficient?

The answer to (*a*) is obtainable only by direct correlation procedure, while those to (*b*), (*c*), (*d*) and (*e*) are normally reached after algebraic and arithmetical computations based upon the results of (*a*) and the inter-correlations between tests.

The recognized procedure is that of partial regression and multiple correlation, as developed by Udny Yule and Karl Pearson. Pearson in particular directed attention to the fact that the formulæ developed by him for dealing with statistical selection (of which, as has recently been shown, partial correlation is merely a special case) can readily be interpreted in terms of spherical trigonometry, and printed a graph for dealing with the simplest cases of all[1]. To avoid and illustrate the somewhat elaborate algebraic manipulations which multiple correlation involves, several other observers have used or suggested a graphical procedure. Kelley has proposed a simple 'alignment chart'[2]; for analogous problems in factor analysis Garnett has proposed to take cosines of angular distances to measure correlations (the basis of Thurstone's 'graphical rotation'); Burt has used the same principle with spherical trigonometry, using a 'globular' projection to obtain a two-dimensional representation[3].

All these methods, however, are admittedly somewhat cumbersome: Pearson's full procedure, for example, required the use of a spherical trigonometer; and none has come into general use for practical purposes. Accordingly it is suggested that the following procedure will be found of great practical use. The chief novelties are (i) the use of a stereographic projection, and (ii) the combination of a graphical procedure with certain approximate equivalences similar to those used by Kelley in building up his multiple correlations. The method has already been used in selecting psychological test batteries of the ordinary type, and found sufficiently reliable for most practical purposes.

As with most other graphical methods, the underlying assumption is that the related variables can be represented by axes in space inclined to one another at angles the cosines of which are the respective correlation coefficients. On this basis three such variables may be represented as the angular points of a spherical triangle *ABC* (the points where such directions emerge from the sphere the centre of which is the point of radiation). The sides of the triangl *a*, *b*, and *c*, represent the primary correlations r_B r_{CA} and r_{AB} respectively, while its angles *A*, *B* and represent the partial correlations $r_{BC.A}$, $r_{CA.B}$ an $r_{AB.C}$, using the usual notation. It can then b shown that the perpendiculars from the vertices t the opposite sides represent the multiple correlation $R_{A(BC)}$, $R_{C(AB)}$ and $R_{B(CA)}$; and the points whe these perpendiculars meet the opposite sides indicat the combination of each pair of variables whic correlates best with the remaining one. The weighting of standard scores for each pair of variables to produce the best correlation with the remaining one i in inverse proportion to the cosines of the angles a the points represented by the tests themselves, that is

$$\frac{\text{Weighting } A}{\text{Weighting } B} = \frac{\cos B}{\cos A}.$$

With the aid of a stereographic net, it is possible to cope with the three-dimensional problem on two dimensional paper. The stereographic net as used in mineralogy or cartography is simply one of many devices which enables all points on the surface of a sphere to be represented on one plane, so that the angular distances between them may be read off directly in terms of any appropriate angular function; in this case the appropriate function is the cosine rather than the angle itself, and a net graduated in cosines is used in place of one graduated in degrees

The method suggested below for estimating multiple correlations for *more* than two tests and a criterion differs from the more accurate but lengthier algebraic one, in that combinations of tests are built up successively instead of simultaneously. However, if care be taken to begin with the pair of tests which correlate best with the criterion (and, so far as is practicable, least with one another) the degree of error introduced in the succeeding steps appears to be in practice quite small in the case of ordinary aptitude test batteries. Moreover, the observed graphical result is slightly *less* than the possible maximum, so the estimate is conservative and safe to use; for example, in an example quoted by Holzinger[4], concerning relation of Beta tests to Stanford Binet as a criterion, the stereographic method indicates that a multiple correlation coefficient of 0·72 could be obtained by the use of Tests 4, 7 and 3, whereas the computed value for the whole battery is given as 0·731. Garrett[5] works an example to estimate multiple correlation between three variables in combination and a criterion. His numerical result for the best combination is 0·83. The stereographic method gives proportions of 3, 2 and 1 as the values for approximate weighting of the three independent variables, 0·80 for the multiple correlation obtained by using these weights, and 0·72 as the correlation obtained by using unweighted scores. These examples are given to indicate the usual magnitude of error that has been observed by the Aptitude Testing Section of the R.A.A.F., where the method has been used for preliminary trials, the exact figure being afterwards computed for that particular combination which these trials show to be the best.

A theoretical justification of the procedure proposed for determining the multiple correlation may be given in terms of spherical trigonometry as follows. The deduction is based on a proof suggested by Prof. C. Burt; but the practical justification for the procedure proposed rests chiefly on its evident effectiveness as judged by a long series of trials with actual data. Actually, the use of the net for graphical work quite mechanical, and requires no special skill, ce the three-dimensional principle is appreciated. practice, the graph is plotted on transparent paper perimposed on the stereographic net, and rotated out the 'origin' by means of a pin stuck through e centre of the net.

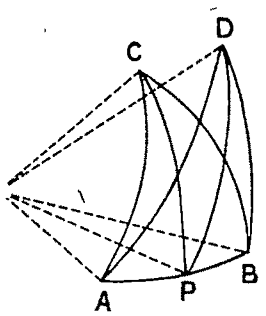

Fig. 1.

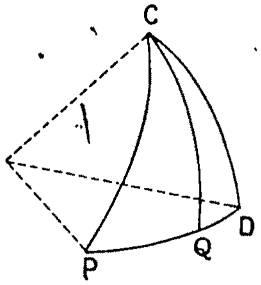

Fig. 2.

Consider a case of three tests A, B and D and iterion C.

Step 1. In Fig. 1, ABC is a spherical triangle the ides of which are made to represent the inter-orrelations of A, B and C, that is, the cosines of he arcs are the correlation coefficients. CP is drawn at right angles to AB. Then CP may be shown to represent the multiple correlation $R_{C(AB)}$, thus:

In the triangle ACP,

$$\sin \angle CAP = \frac{\sin \text{arc } CP \sin \angle CPA}{\sin \text{arc } AC}.$$

But $\sin \angle CPA = 1$. Hence the equation may be rewritten

$$\begin{aligned}
\sin \text{arc } CP &= \sin \text{arc } AC \sin \angle CAP, \\
\sin^2 \text{arc } CP &= \sin^2 \text{arc } AC \sin^2 \angle CAP, \\
1-\cos^2 \text{arc } CP &= (1-\cos^2 \text{arc } AC)(1-\cos^2 \angle CAP) \\
&= (1-r^2_{AC})(1-r^2_{CB.A}).
\end{aligned}$$

$$\text{But } R_{C(AB)} = \sqrt{\{1-(1-r^2_{AC})(1-r^2_{CB.A})\}}$$

$$\text{Hence } \cos CP = R_{C(AB)}.$$

Step 2. In Fig. 1, on the same base AB, the triangle ABD is drawn representing the relationship between the three variables A, B and D. D is joined to P, such that the arc DP now represents the relation between D and P (that is, the combination of A and B most closely related to C).

Step 3. A new spherical triangle is now drawn (for the sake of clarity) in Fig. 2. In this triangle the base is PD (transferred from Fig. 1), and the other sides are PC (also transferred from Fig. 1) and DC representing the relation between D and C. CQ is now drawn perpendicular to PD, meeting it in Q.

Now, in the triangle CPQ, we have

$$\sin \angle CPQ = \frac{\sin \text{arc } CQ \sin \angle CQP}{\sin \text{arc } PC}.$$

Since $\angle CQP$ is a right angle, this may be rewritten:

$$\sin \text{arc } CQ = \sin \angle CPQ \sin \text{arc } PC.$$

But in Step 1 we have already shown that $\sin \text{arc } PC = \sin \text{arc } AC \sin \angle CAP$.

$$\text{Therefore, } \sin \text{arc } CQ = \sin \angle CPQ \sin \text{arc } AC \sin \angle CAP.$$

$$\text{Therefore, } 1-\cos^2 \text{arc } CQ = (1-\cos^2 \angle CPQ)(1-\cos^2 \text{arc } AC)(1-\cos^2 \angle CAP).$$

Now $\cos \angle CAP = r_{CB.A}$, and similarly $\cos \angle CPQ = r_{CD.P}$; or, in other words, $r_{CD.AB}$, since P may be taken as representing A and B simultaneously. (This is, of course, only an approximation. P represents the *weighted* sum of A and B, and eliminating a weighted combination is not quite the same as eliminating A and B by the usual formula.)

Cos arc AC is, of course, r_{AC}.

Hence the equation becomes:

$$\cos \text{arc } CQ = \sqrt{\{1-(1-r^2_{CD.AB})(1-r^2_{AC})(1-r^2_{CB.A})\}}.$$

This is in the form of the equation for multiple correlation; and yields a procedure for estimating $R_{C(PD)}$ as an approximation to the true multiple correlation $R_{C(ABD)}$.

As pointed out earlier, the weights to be attributed to each test are represented inversely by the cosines of the base angles. (With the stereographic net, the cosine values may be obtained by the use of the 'meridians' as distinct from the 'parallels'. Another approximation is involved here at stages *beyond the first combination*, for then the partial regression coefficients are not quite equal to the partial correlations.) Thus, the relative weights for A and B used in the combination can be obtained exactly from the triangle ABC while the proportion of weighting of (AB) to D can be obtained from the base angles of the triangle PCD (Fig. 2). From this, the composite weighting for A, B and D can easily be estimated. This also will not be quite exact as the relative weights of A and B will be the same in the final result as they were before test D was added to the combination. However, since A and B are the tests making the greatest contribution, it is clear that the total error involved will be small; and less than that which would occur if the tests were combined without regard to weighting at all.

A simple extension of this method in which instead of perpendiculars, lines (arcs of great circles) are drawn from the vertices to the mid-point of the base, enables a value to be estimated for the multiple correlation coefficient which would be obtained by combining the tests in equal proportions. This may, if necessary, be compared with that obtained by the more accurate method in order to establish the advantage in the particular circumstances of using the weighted as distinct from the unweighted test combination.

In the case of analysing the relationships between tests of a large battery, the process of projecting them as points with reference to a base-line consisting of any two of the variables is quite illuminating, especially if something definite is already known about the variables used as the base. By changing the base several times and replotting, the tendency of certain tests to form 'inseparable' pairs or groups may be qualitatively and quantitatively examined.

I gratefully acknowledge the assistance given by Prof. Cyril Burt in discussing the problems considered in this paper, but do not wish him to be held responsible for any inconsistencies in the final presentation.

INDIGENOUS FORESTS OF NEW ZEALAND

IT is rather illuminating to realize that some of our English characteristics are just as strong in a Dominion. The 'hands off the New Forest' controversy when the Forestry Commission suggested undertaking certain operations will be remembered. Beauty spots in that region or elsewhere in Great Britain may chiefly depend upon the presence of a clump or block of old trees—very beautiful things. The argument is that it would be desecration to touch them. Since the trees will not stand for ever, this means that our children or grandchildren will never see that particular beauty spot.

In the report for 1944 of the New Zealand State Forest Service (Gov. Printer, Wellington, 1944) the attitude has arisen on a larger scale. New Zealand has still left a considerable area of its old indigenous forests, although exotic conifers have been planted on a very extensive scale. Arising from the admirable soil conservation schemes now under consideration in the Dominion is one aspect which constitutes a serious threat to these national forests. It is the 'hands off' policy once again. "Well meaning but unrealistic enthusiasts," says the report, "advocate a lock-up-use-not policy of forest reservation, under the mistaken impression that such a practice will perpetuate the principal indigenous species—such as rimu, matai, etc. The exact reverse would occur in most forests. Why do so many of our rimu forests consist of virtually only old trees with seedlings and medium-age trees so few as to be insignificant? The initial cause is the fact that, no matter how prolifically the old trees seed, the humus on the floor is so thick that even when the seeds germinate, roots are seldom able to penetrate to the mineral soil beneath, and most seedlings therefore die." The Director of Forestry, continuing, points out that owing to the density of shade such seedlings as do develop gradually die from want of light, while in other parts of the forests inferior species capable of standing more shade are ousting the more valuable ones.

The Director deals with the whole matter clearly, giving a sylvicultural exposition with which a forestry student is well acquainted at the end of his first year's study—data so little known in spite of their elementary nature that ignorance thereof is imperilling the future of the Dominion's indigenous forests. Controlled logging and fire protection are advocated as the methods to be introduced. It is the logging, that is, felling any of the trees, which the opponents object to. The answer is a condemned and disappearing forest.

In connexion with this logging in indigenous forest, an almost inevitable discovery has been made, meriting consideration outside New Zealand. New plywood factories were to provide plywood for defence works and a junior technical officer of the Forest Service was stationed at one of these to assist in the solution of current problems in the manufacture of both casein- and resin-bonded plywood for defence works. Marked advances in manufacturing technique have been made, but there is said to be room for improvement. The tentative conclusion has been arrived at that the high moisture content of rimu and other indigenous logs makes it extremely difficult to dry their veneers in standard driers and at the rates, temperatures and humidities usually employed in plywood manufacture. On the subject of peeler-logs, it has been established that t quality of the local product, if it is to comp successfully with imported plywoods on a qual basis, will have to be improved. Straightness grain and reasonable freedom from defects essential to the production of sheets free from tw and warp, etc.

This applies equally to the logs used in the plywo mills in Britain, where most of the material used imported. It is the forest officer's business to s that only suitable logs are ear-marked for plywo conversion. As to the standard driers, New Zeala might learn something in this direction from Ind at the Forest Research Institute, Dehra Dun; f departures from European practice both in patte of drier, temperatures, humidities and length of tin of remaining in the drier are in practice in th country.

E. P. STEBBING.

BRITISH ARMY VETERINARY SERVICES IN THE FAR EAST

A PREVIOUS note (*Nature*, Jan. 13, 1945, p. 6 described the great responsibilities and hig quality of the work of the Army Veterinary Servic in the Near East. In the Far East, says Brigadie E. S. W. Peatt (*Vet. Record*, May 12, 1945, p. 219 even greater responsibilities are being undertake The campaign in Burma made necessary a return t animal transport, and this fact, together with th duty of providing fresh meat for the troops, mad necessary an organization for the care of a grea variety of animals. The result has been that th British and Indian veterinary personnel has increase to ten times its pre-war strength and further increase are likely.

Adequate training in veterinary tropical medicine was an early problem, and in October 1942 the Indian Army Veterinary Corps Training Centre was established. Its Officers' Training School now gives a training lasting two months to fifty officers at a time and its training wing gives to 1,200 men at a time a course lasting five months. Both courses are designed to produce competent soldiers as well as competent veterinary personnel, because the necessity of military as well as veterinary training has often been demonstrated in the fighting in Burma and Arakan. Farriers are trained in the Army Veterinary School; the classes consist of twenty-four students and extend over sixteen weeks, this training being continuous throughout the year. The same School gives continuous instruction in veterinary first-aid, animal management and the care of cattle, sheep and goats purchased for slaughter.

The care of transport animals used for military purposes involves the care of horses, mules and donkeys used in operational areas; the care of bullocks used on peace stations so that horses and mules can be released for operational work; the care of the camels, which are restricted by climatic conditions to the North-West Frontier and the Punjab; and the care of elephants used in the Burmese jungle. But, in addition to all this work, the Army Veterinary Service has the important responsibility of the control of the military dairy farms, and it has been necessary to set up a separate veterinary organization to deal with these. The Military Dairy Farms Department has increased its milch cattle from 10,000 to more than 60,000, and to-day it is probably the biggest ry organization in the world. Although there are) million cattle in India, the provision of fresh at for the troops is made more than usually ficult by the climate, the enormous distances olved, the many infectious diseases and the fact at Indian animals are not bred and fattened for ughter. Several hundred thousand animals are ught each year for slaughter, and the Army terinary Service examines and selects them and res for their health. Many animals must spend m three to ten days in the train before they reach eir destinations. Slaughter stock are transported sea voyages which may last from one to five days, train, by motor, on foot or by a combination of four methods; and the hot weather, traffic con- stion, compulsory use of all-metal wagons and her factors increase the difficulties of organizing ch journeys. Animals are never kept in the train r longer than forty-eight hours; but the rests be- een spells of travelling expose them to the many fectious diseases of the Far East.

A further responsibility of the Army Veterinary rvice is the breeding, through local development hemes, of pigs, rabbits and poultry, and these imals present their own disease problems. The rmy Veterinary Service also inspects the meat and rovides the Veterinary Wing of the Chemical Defence esearch Establishment, which deals with the defence f animals against gas warfare. The Army Veterinary aboratory Services and their mobile laboratories repare vaccines and undertake routine and other iagnostic work. Nowhere else in the world, says rigadier Peatt, does the veterinary officer encounter uch a variety of diseases. A good example of the ilitary importance of these diseases is the outbreak f the equine trypanosomiasis called 'surra' in 1942 n the Assam-Burma border. At one time 17 per ent of the horses and mules were put out of action y this disease, but the control measures adopted educed the percentage of infected animals from 17 per cent in 1942 to 7 per cent in 1943 and 2 per ent in 1944. The Army Veterinary Service devised the method of injecting 'Antrypol' intravenously and obtained by this method 90 per cent of recoveries from this disease. Anti-surra units have now been formed.

Two other important diseases are anthrax and rinderpest, against both of which all cattle purchased and many sheep and goats are immunized. Rinderpest is the most important cattle disease in India. Although many thousands of cattle owned by civilians have died near the military dairy farms, the losses on these farms have been negligible (less than 1 per cent in 1943–44). Outbreaks of glanders have been quickly controlled, epizootic lymphangitis and strangles are being studied, precautions against foot-and-mouth disease, which is extremely widespread in India, are being taken, and the control of variola, which is usually introduced to dairy farms by buffaloes which have been bought, is being improved. Among the serious diseases of the smaller animals are pasteurellosis, salmonellosis and Ranikhet (Newcastle or Doyle's disease), and research upon the control of these is being done.

It is clear that the Army Veterinary Service is doing in the Far East a fine job which is vital to the success of the war against Japan. The quiet efficiency and progressive spirit of this work show how much the veterinary profession can contribute to the solution of the vast food problems of the post-war world.

G. LAPAGE.

ARTS AND CRAFTS OF THE COOK ISLANDS

In a large and profusely illustrated volume the Director of the Bishop Museum gives a comprehensive and detailed account of the material culture of the Cook Islands*. The Polynesians are known for their clever workmanship and, as the illustrations show, these islanders are no exception, whether they are carving wood or plaiting fibres. The greater portion of the book is concerned with a description of the arts and crafts, including religious symbols, and this is followed by a discussion of their implications.

A study of the material culture of the Cook Islands shows that there are three cultural periods, a fact that may be best understood by the racial history of its inhabitants. The Polynesian ancestors, as it is now recognized, came from the mainland of Asia into Indonesia where they adjusted their continental culture to suit volcanic islands the fertile soil of which produced abundant food and where a rich culture developed. From Indonesia they passed on to Micronesia, the coral atolls of which formed a barren contrast; arts and crafts suffered drastic changes owing to the loss of food plants and raw material of wood and stone, and the people retrogressed from the stone age to a shell age. From here these ancestors, in the course of ages, moved westwards and finally arrived at the Society Islands, where they were once more on volcanic soil, so that stone was again available and the rich soil provided ample food. On these islands the Polynesians settled and from them they radiated out to the various island groups they were destined to colonize. They rediscovered the use of stone, and food plants and animals were probably introduced from the Melanesians in Fiji.

It was in this period of expansion that the Cook Islands were settled—roughly six hundred years ago—the culture being identical with that of the parent colony of the Society Islands, and this forms the first phase. Modifications and local developments have naturally taken place in both island groups so that it is difficult to give an exact picture of this early stage, but certain elements can be reconstructed. Some cultural processes, which may be regarded as stable, persisted unchanged until European occupation; examples of these are the plough method of firemaking and the earth-oven. The second period was one of developments rather than of any very sudden change. These may be due to diffusion owing to migration or importation or they may be caused by the substitution of another material or technique. Occasionally a new local technique is invented, such as the decorated borders to the pandanus sleeping mats that are peculiar to the Cook Islands.

The third period begins with the arrival of the white people. Early European voyagers bartered hoop iron and axes for fresh food, and the natives were quick to realize the superiority of metal over stone and to acquire it whenever possible. With the coming of the missionaries clothing was altered both in design and in material, and as time went on most of the old culture became obsolete. The new generation has grown up under these changed conditions and the cultural invasion is firmly established, for the natives will not give up the material comforts of to-day for any mental satisfaction connected with a sentimental past.

K. RISHBETH.

FORTHCOMING EVENTS

Wednesday, July 18

Institution of Mining Engineers (at the Midland Counties Institution of Engineers, Nottingham)—Fifty-first Annual General Meeting. Mr. T. E. B. Young and Mr. W. H. Sansom: "Simultaneous Cutter and Loader for Longwall Mining".

Royal Institute of Chemistry (Birmingham and Midlands Section) (in the English Theatre, The University, Edmund Street, Birmingham), at 6.30 p.m.—Dr. Dorothy Jordan-Lloyd: "Protein Fibres".

Friday, July 20

Biochemical Society (in the School of Medicine, Thoresby Place, Leeds 2), at 2.30 p.m.—Scientific Papers.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Teacher of General Engineering Subjects (including Electrical), in the Bootle Municipal Technical College and Boys' Secondary School (Trinity)—The Director of Education, Education Offices, Town Hall, Bootle (July 20).

Civil Engineers by Control Commission for Germany: (*a*) Assistant Controllers (Ref. E.1677 A) with wide experience in Civil Engineering Design and Construction, including Water Supply, Sewage Disposal, Civil Engineering Plant and Building Construction; (*b*) Chief and Senior Technical Assistants (Ref. E 1680.A) with good experience in Civil Engineering work in some or all of the following—Water Supply, Sewage Disposal, Civil Engineering Plant, Building Construction, Demolition and Recovery of Salvaged Material—The Ministry of Labour and National Service, Room 670, York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (July 20).

Lecturer in Mathematics—The Principal, Derby Technical College, Normanton Road, Derby (July 20).

Lecturer in Mechanical Engineering with special knowledge of Hydraulics and/or Aeronautics, a Lecturer in Mechanical Engineering, and a Lecturer in Engineering Drawing—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (July 21).

Lecturer in Physiology and Anatomy, mainly to Sister Tutors—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (July 21).

Teachers (2) for Science and Mathematics at the East Ham Technical College—The Chief Education Officer, Education Office, Town Hall Annexe, Barking Road, London, E.6 (July 21).

Assistant (temporary) to the Advisory Bacteriologist—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (July 21).

Assistant Lecturer in Physics, and a Demonstrator in Zoology—The Registrar, University College, Nottingham (July 21).

Teachers of Engineering Subjects with special qualifications in (*a*) Heat Engines, (*b*) Electrical Engineering, and (*c*) Production Engineering, in the Municipal College—The Chief Education Officer, 215 High Street, Smethwick (July 23).

Lecturer in Economics—The Secretary, Queen's University, Belfast (July 24).

Transport and Mechanical Engineering Assistant (temporary)—The Town Clerk, Town Hall, Camberwell, London, S.E.5 (July 25).

Chair of Pharmacology, tenable at the College of the Pharmaceutical Society—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (July 26).

Assistant Municipal Engineer by the Accra Town Council, Gold Coast—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting E.1174.A (July 27).

Engineers, Physicists and Applied Mathematicians at the Building Research Station, Garston, Watford, for research and other technical work on Building—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting D.S.I.R. (July 28).

Deputy Secretary—The Secretary, Institute of Fuel, 30 Bramham Gardens, London, S.W.5 (endorsed 'Deputy Secretary') (July 30).

Assistant in Botany—The Secretary, The University, Aberdeen (July 30).

Assistant Engineers—The Clerk to the Metropolitan Water Board, New River Head, Rosebery Avenue, London, E.C.1 (endorsed 'Assistant Engineer') (July 31).

Educational Psychologist (part-time) at the Preston Child Guidance Clinic—The Director of Education, Municipal Building, Preston (August 9).

Lecturer in Mathematics in the University of Tasmania—The Agent-General for Tasmania, Australia House, Aldwych, London, W.C.2 (August 15).

Assistant Registrar—The Registrar, The University, Liverpool (August 15).

Principal of the Sir John Cass Technical Institute—The Correspondent, Sir John Cass's Foundation, 31 Jewry Street, London, E.C.3 (August 31).

Professor of Metallurgy—The Registrar, King's College, Newcastle-upon-Tyne (August 31).

Secretary and Librarian—The Director, Institute of Historical Research (University of London), Tavistock House South, Tavistock Square, London, W.C.1 (August 31).

Medical Officer to the University—The Secretary, The University, Edmund Street, Birmingham, 3 (September 3).

Lecturer in Dental Pathology and Bacteriology—The Registrar, The University, Liverpool (September 30).

Grade III Assistant Lecturers (2) in Applied Mathematics—The Registrar, The University, Liverpool (October 1).

Nuffield Chair of Child Health, tenable at the Institute Child Health—The Academic Registrar, University of London, Ri mond College, Richmond, Surrey (October 1).

Chair of Moral Philosophy—The Secretary of University Cou The University, Glasgow (October 15).

Lecturers in Natural History, Natural Philosophy, Chem try, Mathematics, and Statistics—The Secretary, The Universit Aberdeen (October 15).

Teacher of Mathematics and English with History or Ge graphy as subsidiary, and Teachers (2) of Engineering Subjec (Mathematics, Science and Drawing) up to National Certifica standard—Miss P. E. Roberts, Art and Technical Institute, Yeov Somerset.

Lecturer in Physical Chemistry in the Victoria Universi College, Wellington, New Zealand—The Secretary, Universiti Bureau of the British Empire, c/o University College, Gower Stre London, W.C.1.

Chief Laboratory Steward in the Chemistry Department—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, Londo S.E.18.

Industrial Investigators (graduates, men or women), a Vocational Advisers (graduates, men or women)—The Directo National Institute of Industrial Psychology, Aldwych House, Aldwyc London, W.C.2.

Adviser in Psychology to the Government of India in the Ho Department—The Secretary, India and Burma Recruitment, Ind Office, Whitehall, London, S.W.1.

Head of the Biology Department—The Principal, Harper Adam Agricultural College, Newport, Shropshire.

Assistant Masters (*a*) to teach Mathematics in the Junior Tec nical School and to day-time released students up to Higher Nation Certificate standard, (*b*) to teach Physics and Chemistry in th Junior Technical School and Chemistry to part-time students up t National Certificate standard, in the Corby Monotechnic Institut and Junior Technical School—The Chief Education Officer, Count Education Offices, Northampton.

Assistant Chemist at the Langford Treatment Plant and Labora tory, Maldon—The Engineer, Southend Waterworks Company, 1 Cambridge Road, Southend-on-Sea.

SCIENCE AND NATIONAL DEFENCE*

IMPORTANT as it is that there should be worked out as speedily as possible an adequate national defence policy embodying all the lessons and experience of the last five years, no such policy can be formulated in isolation. It should be ensured of the support of all political parties in Britain, and it must also be related to the policies of other members of the British Commonwealth and of the United Nations. That much was clearly recognized in the debates in the House of Lords, in Lord Vansittart's plea for a permanent Inter-Allied Committee of Scientists to examine and control the use of any scientific discovery or invention considered dangerous to the safety of mankind, in Lord Strabolgi's proposal for pooling knowledge of scientific discoveries and inventions, in Lord Cherwell's reply, and in Lord Brabazon's plea for an international committee with full powers of investigation anywhere in the world. What is encouraging, however, is the evidence of the extent to which these problems are already occupying the minds of others of the United Nations, and notably in the United States.

The parallel in thought between the report of the Select Committee on National Expenditure and the address of the Hon. Robert P. Patterson, U.S. Under-Secretary for War, on "Science and Industry in National Security" (see *Nature*, 154, 785 ; 1944) is unmistakable. A recommendation for the establishment within the National Academy of Sciences of a Research Board for National Security has already come from the Committee on Post-War Research, as was stated by the U.S. Secretaries of War and the Navy on February 12, 1945, in which these facts are recognized. Further, Dr. J. B. Conant has lent the weight of his authority to a proposal for the establishment of an international civilian technical inspectorate in which a tradition might be built up anchoring professional loyalties to an association of nations. Dr. Vannebar Bush in his recent report as president of the Carnegie Institution of Washington touches briefly on this same question of defence and its relation to scientific research, and the imperative necessity of continuing attention to the possible military applications of expanding science. Different aspects of the problem are also discussed in an able article, "Science and Foreign Policy", by the American expert, Mr. G. Fielding Elliot, in *Foreign Affairs* of April last, from which Lord Vansittart quoted, and in the study, "The Control of Germany and Japan", by H. G. Moulton and L. Marlio, which the Brookings Institution of Washington published last year.

Mr. Elliot raises the fundamental question whether the discoveries of science must not now become the common property of all for the use of all, and whether we can afford any longer to tolerate private research for military purposes, or commercial processes serving those purposes. The robot-bomb, the rocket and the jet-propelled plane demonstrated the dangers which must be guarded against, and no international organization for world security will be adequate which does not possess the ability to deal with such dangers at the source.

---

* *Continued from p. 31.*

Mr. Elliot urges that the foundation of successful partnership in international affairs, as elsewhere, is good faith and mutual confidence ; and he suggests therefore that the first step to security is the exchange of full information regarding the armed forces. Already we have seen that modern warfare involves the mobilization of all national resources, and that science has introduced into warfare a succession of new weapons of steadily increasing range, speed and destructiveness. Nevertheless, Mr. Elliot believes—and the trend of Lord Cherwell's speech would seem to indicate his concurrence—that if the results of the labours of all scientific men in the peace-loving States were pooled, the chance of sudden surprise would be greatly reduced, since science in different countries generally advances on parallel lines.

Mr. Elliot does not ignore the difficulties that may have to be overcome in securing the complete and continuous interchange of information on the progress of scientific research among the United Nations. He puts a question mark against the attitude of the U.S.S.R., though here the appointment of Prof. Eric Ashby as scientific attaché at the Australian Legation in Moscow may mark the beginning of some closer contact between that country and the Western nations. The matter is so important that it is all the more unfortunate that the Government should have considered it necessary on any ground to refuse exit permits to British men of science who had accepted invitations to attend the two hundred and twentieth anniversary celebrations of the Soviet Academy of Sciences.

Mr. Elliot points out clearly all that is involved in such interchange—freedom of communication, travel, the Press, radio, and academic and scientific interchange—and if such a policy is the soundest from the point of view of national defence, it is the policy also which is most stimulating to creative thought and fundamental research. Such objectives are widely recognized as claiming the steady support of all scientific workers, but to attain them much more will be required than the maintenance of the machinery for Anglo-American collaboration and exchange of scientific and technical information set up during the War, or even the relaxation of the censorship. Much will depend on the readiness with which the U.S.S.R. abandons her 'Chinese wall', and clear thinking will be required to deal with the problems which arise out of the relation between scientific research prompted by commercial competition and military affairs, patent law and the like. Mr. Elliot notes that we must be prepared to find that the solution may involve much loss of individual freedom and some curtailment of the search for commercial or military advantage.

Only some of the problems that arise in the technical control of Germany and Japan are indicated very briefly by Mr. Elliot. Those problems are closely analysed in a recent book* by Dr. H. G. Moulton and Dr. L. Marlio, who, considering first the lessons of the Treaty of Versailles, suggest th measures for economic control must be based on tw guiding principles : first, the economic devices mus not be permitted to throttle the economic life of th country on which they are imposed ; and secondly the measures selected must be administratively feasible and relatively easy to enforce. On these ground they regard, for example, the complete destruction o the chemical industry of Germany as impracticable the only strategically key industry which holds sufficient possibilities of effective control to merit favou able consideration is the electric-power industry.

Drs. Moulton and Marlio reject the idea of permanent military occupation as well as of economi controls, and propose that reliance should be place upon a system of detection and coercion by punitiv measures if infringements are discovered. For thi purpose they propose the creation of a Rearmamen Detection and Prevention Board comprised chiefly o military officials, and in the nature of an extension o the war-time Combined Staff Organization. The Boar would be the executive agency for the general policie and procedures regarding military controls determined by the governments at its establishment, bu it should possess the power of independent action within the field so defined. It should be empowered to maintain within key industrial areas sufficient supervisors to detect evasions of the disarmament provisions, to direct the attention of the German or Japanese Government to any evasions discovered and to apply the necessary coercive measures if such warning is not promptly heeded.

There may be some grounds for doubt as to whether we can wisely rely on a system of detection and coercion alone ; Drs. Moulton and Marlio are not altogether convincing in their demonstration of the impracticability of economic control, and their two principles can be stretched too far ; but that some measure of inspection must be worked out and systematically applied is scarcely open to challenge. Any such system will almost certainly function more effectively when the free interchange of scientific and technical information and exchange of personnel is carefully fostered ; and for this reason the development of the British Central Scientific Office in Washington, the American Scientific Office in London, the Anglo-Soviet Science Collaboration Committee and the Scientific Co-operation Office of the British Council in China into something of an international science co-operation service, as suggested by Dr. J. Needham (*Nature*, 154, 657 ; 1944), may be a measure of the first importance from the point of view of defence.

It is for men of science to stress the importance of this aspect of the matter at the present time. Mr. Lyttleton, in the House of Commons on June 13, admitted that the free flow of scientific information in an industry is absolutely necessary. The free flow of scientific and technical data in a nation and between nations is equally essential to world security, and to encourage, as Sir Arrol Moir suggested in the *Engineer* of June 2, the fullest possible inventiveness in time of peace.

Rapid progress in this matter, as Mr. Elliot observes, can scarcely be expected, but scientific orkers should miss no opportunity of educating oth public opinion and Government as to its nportance. A system of scientific attachés could do uch to stimulate the free flow and interchange of formation and of men and women, and to avoid cidents like that in connexion with the Soviet cademy of Sciences, which tend to jeopardize good elations. But while endeavouring to secure a wider nderstanding of the contribution of science to ational defence and the conditions in which that ontribution can be made most effectively, they hould lend the full weight of their influence as itizens to secure urgent attention to the formulation f defence policy on lines above the turmoil of party olitics, and to stimulate the clear thinking required. They could help in emphasizing certain principles which an adequate defence policy must embody : the retention of an adequate Combined Staffs Organization, not only of the different armed services but at least between Britain, the United States and the U.S.S.R. ; the determination of the peace strength of the armed forces in accordance with the possible rate of development of full war potential, the strength of the other principal Powers and our geographical strength, and in appropriate relation with our foreign policy, so that strength which can only be changed very slowly is in accord with policy, so far as that can be set by looking well ahead.

* The Control of Germany and Japan. By Harold G. Moulton and Louis Marlio. Pp. xi+116. (Washington, D.C.: Brookings Institution; London: Faber and Faber, Ltd., 1944.) 10s. net

These are some of the principles emerging from the experience of the last twenty-five years ; and the Select Committee's recent report provides scientific workers with admirable material for their task of education. That there should be so much evidence on both sides of the Atlantic that the same conclusions are being reached provides ground for the hope that there will this time be thrashed out a national policy for defence which is in harmony with our commitments and our foreign policy, in which the various elements are in balance one with another and appropriate use is made of all the nation's resources of materials, man-power and intellect. No defence policy, no system for the control of Germany or Japan, will be effective which does not provide for attracting men of the highest ability into the armed services and the scientific and technical services of the United Nations, for the adequate prosecution of research and encouragement of inventive ability, and for the fullest and widest possible dissemination of scientific and technical information. Closer co-ordination is essential between the departments and other agencies or institutions within Great Britain and with such organizations as the National Academy of Sciences, the National Research Council, and the Office of Scientific Research and Development in the United States, possibly through a Central Scientific and Technical Board as suggested at the recent Conference of the Association of Scientific Workers. The free exchange of knowledge across national boundaries, upon which creative thought has always largely depended, and which now may well provide one of the strongest safeguards against those dangers of which the robot-plane and the long-range rocket have given so dire a warning, is still one of the fundamentals of a free society.

CHEMICAL ANALYSIS AND STRUCTURAL DIAGNOSIS BY INFRA-RED ABSORPTION

Infrared Spectroscopy

Industrial Applications and Bibliography. By R. Bowling Barnes, Robert C. Gore, Urner Liddel and Van Zandt Williams. Pp. vi+236. (New York: Reinhold Publishing Corporation, 1944.) 2.25 dollars.

THAT modern wars lead to scientific development is a commonplace more vividly borne out in the present War than in any other. Now that the silences may be broken, applications of physical techniques become evident which may be equally important in times of peace. Infra-red spectroscopy has been transformed during recent years from a delicate and exacting technique into a more easily controllable robust tool, which will be of great value in the future for both pure and applied science. Some indications of this have been shown by discussions such as that recently organized by the Faraday Society.

The limitations of secrecy imposed in different lands have varied, and still delay publication of many developments. Dr. Barnes and his colleagues, well known for their past work in the infra-red, and now members of the research laboratory of a leading industrial firm in America, have given us one of the first manuals for workers in this field, and particularly for those who will use infra-red absorption as an analytical technique. The first part of their book is a reprint of a lengthy paper published recently in *Industrial and Engineering Chemistry*, in which the theoretical and experimental principles of infra-red measurements were described, and a range of the spectrum of each of a very large number of molecules was shown graphically for purposes of reference. To this the authors have now added a detailed and excellent bibliography of the subject, which should be valuable to specialists and non-specialists alike.

Infra-red absorption can be applied to the qualitative and quantitative analysis of mixtures of substances, but it can also be used for diagnostic purposes as well. The vibration frequencies of a molecule, which correspond with absorption bands in the near infra-red, are determined in magnitude by the masses of the atomic nuclei and the forces between them, that is, the strengths of the bonds. It follows that molecules with different nuclear configurations will have a different set of vibrational modes, and since all molecules other than a pair of optical enantiomorphs differ in nuclear configuration, the infra-red spectrum can be regarded as a fingerprint of the molecule. Indeed, it is probable that this vibrational spectrum is the most characteristic physical property of a molecule yet measured. In order to analyse a mixture of substances it will simply be necessary to know the spectra of the pure components present. Unless special interactions occur, the spectrum of the mixture is got by simply superposing those of the individual components with the appropriate intensities, and the key bands can therefore be used for either qualitative or quantitative estimation of the individual components.

In spite of this individualistic character of the infra-red spectrum, some linkages or small nuclear skeletons give rise to vibrational frequencies which are not much affected by the remainder of the molecule. In some cases the reason for this is obvious.

Thus, with bonds such as C—H, O—H, or N—H, the light hydrogen atom oscillates against a much heavier residue, the mass of which has little effect on the oscillation frequency. Each of these linkages therefore retains a roughly constant vibration frequency when present in different molecules. The same applies, even if to a less degree, to some other linkages such as the carbon-carbon double bond or the carbonyl group, and a measurement of how much these frequencies deviate from 'normal' values may give a clue to the nature of the rest of the molecule. In some cases, a roughly constant set of frequencies can be associated with a given set of atoms arranged in a definite manner. These are the bases of structural diagnosis.

The authors of this book have explained these principles clearly and in a way which will appeal to those who are wishing to apply a new method of which they have only fragmentary knowledge. They have described an instrument suitable for most industrial work, with the relevant accessories, and have discussed critically the various difficulties which have to be overcome in obtaining accurate results. They have given examples of analyses of different kinds in which either the standard absorption laws can be used, or in which empirical calibration charts have to be set up because of the breakdown of these absorption laws as a result of intermolecular interactions. By means of typical examples they have also considered carefully the magnitude of errors likely to arise in practice.

All these features make the book an admirable introduction to the subject. At the same time there are several points to which the attention of the inexperienced reader should be directed. For example, although the spectrometer described is a good one, marked recent improvements in both thermocouples and recording systems not referred to in this book should perhaps now be taken into account. One of the disadvantages of a single-beam automatic recorder is the fact that absorption bands usually have to be measured against the background energy of the emitter in air. This background of energy will in any event fall in moving towards longer wave-lengths, but in addition the absorption by atmospheric water vapour and carbon dioxide gives rise to a very irregular background over some spectral regions, and in these regions the quantitative measurement of the absorption by a substance is very difficult. The difficulty can be avoided by using vacuum spectrometers, or minimized by the copious use of drying agents, but neither procedure has proved very satisfactory. The most recent way of obviating the trouble is to use a spectrometer in which two equivalent beams of radiation traverse the instrument, one being used as a blank and the absorbing material being placed in the other. After emerging from the spectrometer, each of the beams is directed on to a sensitive thermocouple. The electromotive forces produced are then amplified separately by D.C. amplifiers and finally fed into a potentiometric recorder having a high speed of response, and so devised that a continuous record is obtained directly of the percentage absorption. Several other types of recording device have been tried recently and it may yet be early to decide which is the most serviceable for all purposes, but there seems little doubt that as regards spectrometers the double-beam system has established itself.

The spectral curves shown in this book suffer from the disadvantage that most of them do not extend to wave-lengths beyond 10 μ, or 1000 wa numbers, whereas it is outside this range, namel between 1000–500 wave numbers, that many of t most useful key bands for analytical work are to found. Also it might be inferred from the limit range shown of the spectra of some of the simpl hydrocarbons that suitable key bands for the compounds are hard to find, whereas a more extende study of their spectra leads to the reverse conclusio In the same way experience has shown that a stud of the range of lower frequencies leads to valuab structural correlations.

The authors have wisely directed attention to t fact that curves such as they have shown must n be used directly by other laboratories for quantitativ work depending on intensities, since instrument factors such as resolving power, or impure spectra du to scattering of radiation will lead to inapplicability It is difficult at present to see how this gener difficulty may be overcome, since it implies that eac laboratory must have pure compounds for calibratio work. In some cases high purity may not be essentia but in others it has been found that very sma amounts of contaminants are easily detected in th infra-red spectrum. Indeed, some of the curves show in this book appear to relate to compounds of doubtfu purity; for example, the curve given for polyviny alcohol shows bands at about 1740 and 1260 wav numbers which are almost certainly due to a smal amount of residual polyvinyl acetate from which th sample may have been obtained by hydrolysis.

These shortcomings do not, however, destroy th great value of this book as a convenient working manual, and it will certainly become widely known and used, together with others which may soon be published, by all those concerned with experimental work in this field. H. W. THOMPSON.

SYMPOSIUM ON INDIA

Essays in Anthropology

Presented to Rai Bahadur Sarat Chandra Roy. Edited by J. P. Mills, B. S. Guha, K. P. Chattopadhayay, D. N. Majumdar and A. Aiyappan. (Published for the S. C. Roy Commemoration Committee of the Indian Science Congress Association.) Pp. viii+268. (Lucknow: Maxwell Co., n.d.) 12 rupees.

"ESSAYS in Anthropology Presented to Rai Bahadur Sarat Chandra Roy" was published in India in 1942, but one of the limitations imposed by war conditions has been the unconscionable delay and irregularity with which books from India have reached Great Britain, if at all. In this case, Roy's *Festschrift* did leave the press in time for him to read it shortly before he died in April of that year, and it must have given him much gratification, for he must have appreciated the general high level which these essays as a whole maintain, and to which his own work indirectly had done much to contribute.

There are twenty-one essays in all; of these, about a third of them by Europeans, the remainder by Roy's fellow countrymen. Both the physical and sociological sides of anthropology are represented, but the latter greatly predominate, physical anthropology being limited to three papers: Dr. Eileen Macfarlane, writing on "The New Systematics and Anthropology", sums up the present position in regard to the classification of human racial units—a very lucid and useful exposition. Drs. R. Krishna u and A. Ananthanarayana Ayer contribute a udy at length of South Indian brains, and G. M. urulkar studies briefly "The Abdominal Bulge in ealth (Males)".

Turning to the non-physical contributions we find useful essay on "Basic Concepts in Anthropology" y Mandelbaum which has been evoked in part by orrespondence resulting from the broadcasting of ctures in anthropology direct from a Minnesota assroom. Clearly the study of anthropology is ore popular, or better boosted, in the United States an in Great Britain. Aiyappan writes well on Theories of Culture Change and Culture Contact", s does Prof. Chattopadhyay on "Conflict and Social ehaviour", though the latter's psychological explanation of why the inhabitants of Bengal accepted slam more readily than those of the Agra and Oudh nly really amounts to the fact that the latter had een Hinduized for a longer time.

One of the best essays in the volume is Mrs. Karve's "Some Studies in the making of a Culture attern". She examines the conflict between patrineal and patrilocal institutions on one hand and atrilocal institutions on the other, and discusses he cross-cousin marriage in Maharastra, and the aternal uncle-niece marriage found farther south. he comes to the conclusion that patriliny is an ndigenous institution derived from a primitive unting-gathering complex; and although one may ind difficulty in accepting the theory that it was not an Indogermanic import, one cannot but endorse wholeheartedly her criticism of "the unsoundness of a policy which would impose the same code on the whole of India completely disregarding the cultural nd historical antecedents of different provinces and different castes".

All the essays, of course, are not of the same high level. Radhakumud Mookerjee's attempt to show that the Rig-Veda is not later in time than the Indus civilization of 3000 B.C. fails to convince. He argues that the Hittite deities with names analogous to those of India, Mitra and Varuna, must have been carried to Mesopotamia from India, ignoring the more likely hypothesis of a distribution from some common centre in Iran or near the Caspian. He seems to think, moreover, that the Sumerians and "Dravidians" belonged to a common physical type; but whereas the Sumerians, so far as our evidence goes, seem to have been brachycephalic, Dravidian-speaking India is on the whole emphatically dolichocephalic, and his statement that the Rig-Veda "is the earliest text not merely of India but of the world" does not help one to accept his conclusions without reserve.

W. J. Culshaw writes of "The 'Folk Consciousness' of the Santals", and W. G. Archer of "The Women's Hunt", a periodic phenomenon of Oraon culture which impresses itself on neighbouring tribes as a sort of "cross between a pantomime and a carnival". J. P. Mills deals with "Some Recent Contact Problems in the Khasi Hills", making the problems clear enough but not offering a solution; C. Fürer von Haimendorf writes of "Religion and Ethics among the Konyak Nagas and other Indian Tribes" and in doing so qualifies the conclusions he came to in "Custom is King"; and Elwin writes, informatively again, on "Primitive Ideas of Menstruation and the Climacteric in the East Central Provinces of India". P. G. Shah in "Non-Hindu Elements in the Culture of the Bhils of Gujarat" makes a useful and important contribution to the study of that tribe, the documentation of which has been neglected to an extent out of all proportion to its importance.

The remaining essays—though one seeks in vain, alas, for one by Dr. B. S. Guha—include one on "Bongaism" by D. N. Majumdar, a joint editor who contributes also an introduction giving an account of Sarat Chandra Roy, whose portrait serves as a frontispiece, but is not well reproduced. The volume has an index and is commendably free from misprints. "Essays in Anthropology" is probably the first anthropological *Festschrift* to appear in India. If subsequent ones keep up to the standard set by it they will do well enough.

J. H. HUTTON.

FUNCTIONS OF A COMPLEX VARIABLE

Vorlesungen über allgemeine Funktionentheorie und elliptische Funktionen

Von Prof. Adolf Hurwitz. Herausgegeben und ergänzt durch einen Abschnitt über Geometrische Funktionen, von Prof. R. Courant. Dritte, vermehrte und verbesserte Auflage. (Published and distributed in the Public Interest with the consent of the Alien Property Custodian.) Photo-lithoprint Reproduction, 1929. Pp. xii+534. (New York: Interscience Publishers, Inc., 1944.) 7.50 dollars.

PERHAPS one of the most regrettable consequences of the War, from a purely academic point of view, has been the inevitable loss of touch with current developments in Europe and the accompanying inaccessibility of standard Continental literature. The appearance of a photo-lithoprint reproduction, from the United States, of one of the classical treatises on function theory, which in pre-war years was rightly regarded as an indispensable possession of the pure mathematician, is thus an event of paramount interest and importance.

This volume, in German, containing among its pages all the fundamental theorems and the results of the classical theory of functions of a complex variable, is so well written as to be almost impervious to any sort of criticism, however fastidious.

It is a third and enlarged edition of the original produced by the authors in 1922 and is divided into three principal sections, of which the first two are mainly ascribable to Hurwitz and the last to Courant.

The first section consists of a development from 'first principles' of the Weierstrassian treatment of the theory, the fundamental idea being the complex power-series and its analytic continuations, from which Cauchy's theorem and its corollaries are ultimately derived. A certain amount of special function theory is also included, with particular reference to integral and meromorphic functions.

The second section, on elliptic functions, gives an account of the elementary properties of doubly-periodic functions, proceeding by way of the Weierstrassian functions and theta functions to those of Jacobi and the elliptic modular function and finally to a discussion of elliptic integrals and their transformations.

The last half of the book, comprising the third section, is entitled "Geometrical Function Theory" and deals very comprehensively with a large variety of topics, including Riemann surfaces, Picard's theorem, conformal representation, Dirichlet's principle, Green's functions and the fundamental theorem of Riemann.

J. H. PEARCE.

ELECTRON SHADOW-MICROGRAPHS OF HÆMOCYANIN MOLECULES

By Prof. ROBLEY C. WILLIAMS
AND
Dr. RALPH W. G. WYCKOFF
Department of Physics and the Virus Laboratory,
Department of Epidemiology, School of Public Heath,
University of Michigan

ELECTRON micrographs of bacteria[1] and of virus particles[2] covered with an obliquely deposited metallic film have a three-dimensional appearance that brings out clearly the shapes of these objects. The visibility of small objects appearing in these preparations has been so greatly enhanced by the shadowing technique[3] that we have been led to apply it to the photography of the elementary particles, or molecules, of a number of proteins and high polymeric substances. The present communication describes such experiments carried out on a hæmocyanin.

Purified hæmocyanin was prepared by quantity ultracentrifugation from the 'blood' of the horse-shoe crab, *Limulus polyphemus*, which has already been photographed with the electron microscope[4]. This 'blood' was first cleared by centrifugation for an hour in a field of *c.* 5,000 times gravity, all sedimented material being discarded. The resulting clear blue solution was then ultracentrifuged for four hours in a field of slightly more than 100,000 times gravity to sediment much of its hæmocyanin. This produced pellets consisting of a very firm colourless core overlaid by a blue transparent jelly which dispersed readily in distilled water and was taken as crude hæmocyanin. The solution of the jelly, after a second hour of clearing at low speed, was ultracentrifuged again at 100,000 times gravity to yield homogeneous bluish pellets. Their dispersion in distilled water provided the purified hæmocyanin used for electron microscopy.

In a first series of experiments, serial dilutions of this hæmocyanin in distilled water were placed, as micro-drops, on the surface of collodion-covered metal screens prepared in the usual fashion for examination in the electron microscope. After standing for a minute on the screens, as much as possible of each droplet was withdrawn and the rest allowed to dry. These dried preparations were placed in a vacuum chamber designed for the evaporation of metallic films, and covered with an obliquely deposited film of metallic chromium having a computed thickness of *c.* 70 A. The angle of deposition used in studying hæmocyanin was always such as to make the lengths of shadows ten times the heights of the objects casting them.

Fig. 1 was obtained by photography with an RCA type EMB microscope of an appropriately dilute solution of hæmocyanin prepared in this way. The film of hæmocyanin, which was continuous at greater concentrations, here has begun to break up into its spherical components and to leave empty spaces or holes such as that near the centre of the figure. As the shadows within this hole indicate, metal was evaporated downwards from the top of the picture. At still greater dilutions such areas of unoccupied collodion, which can be recognized by their characteristic pebbly structure of very fine grain and by the shadows cast on them by the surrounding hæmocyanin, increase in size and number, and the hæmocyanin film itself becomes more fragmented, breaks up into islands and ultimately separates into its component particles distributed singly and in small aggregates.

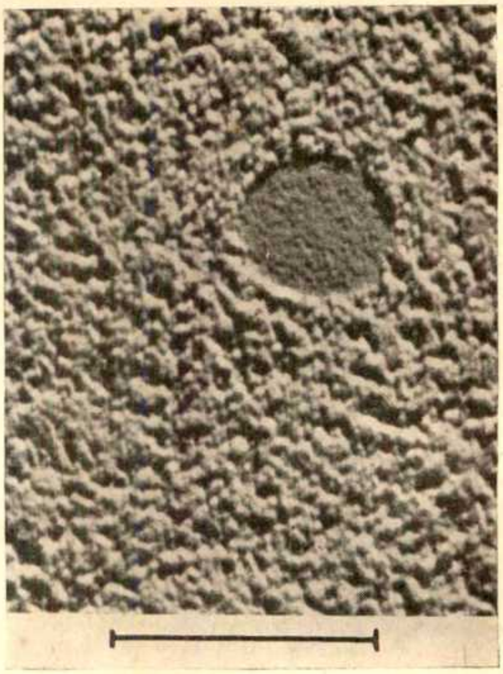

Fig. 1. AN ELECTRON MICROGRAPH OF A DILUTE SOLUTION OF *Limulus* HÆMOCYANIN SHADOWED BY THE OBLIQUE DEPOSITION OF *c.* 70 A. OF METALLIC CHROMIUM.

(Figs. 1, 2 and 3 are negatives; hence regions which appear dark are relatively transparent to electrons. They have each been prepared from the original plates by making an intermediate contact positive on medium lantern-slide emulsion and printing from this on to # 3 Bromide paper. The line at the bottom of each figure represents one micron on the photograph.)

The particles of hæmocyanin are so small that their shapes and dimensions as recorded in such pictures as Fig. 1 must of necessity be considerably altered by the thickness of chromium deposited on their 'illuminated' sides when the angle of shadowing is as great as 10 : 1. In order to give them a truer representation, we have carried out a second set of experiments using gold rather than chromium as the shadowing metal. Gold will deposit as a continuous film when very thin, and because of its great scattering power for electrons will cast adequate shadows in a calculated thickness of only 5–10 A. Fig. 2 is a photograph of a dilute hæmocyanin solution after shadowing with *c.* 8 A. of gold. The hæmocyanin molecules, singly and in small clusters, are clearly evident upon their collodion support.

Though there is no danger of confusing these hæmocyanin molecules with the details of the pebbly collodion background, it is evident that with other smaller macromolecules such a confusion will occur long before one reaches the lower limit of particle size that can be photographed in shadowed preparations. Polished glass has a surface that appears much smoother than collodion, and we have shown[5] that a replica technique can be used to reproduce for lectron micrography both the texture of the glass surface and the size and shape of tobacco mosaic virus protein fibrils deposited on it. A third series of xperiments has been made to see whether or not paricles as small as the hæmocyanin molecules could be investigated successfully with the help of such replicas.

To make these replicas, small drops of dilute hæmocyanin solutions were allowed to dry directly on the cleaned surface of a microscope slide, which was then placed in the vacuum chamber and covered with 6–8 A. of obliquely deposited gold. The areas for study were coated immediately after removal from the chamber with a thin layer (*c.* 500 A.) of collodion. As soon as dry, this collodion and its adhering gold were stripped from the glass and prepared for electron microscopy according to the usual procedures[6] developed for handling metallographic replicas. Because of the great scattering power of the gold compared with organic materials, the replica shows the presence of very small particles regardless of whether or not they are removed from the glass along with the stripped metallic film.

A photograph of such a replica is reproduced as Fig. 3. Comparison between it and Fig. 2 demonstrates that the replica is as successful in showing particles the size of the hæmocyanin molecules as it has been in delineating the tobacco mosaic fibrils. The hæmocyanin molecules appearing in the two figures do not have measurably different sizes and shapes. The background of the replica is more uniform because of the smoothness of the glass surface, and because the fine structure of the unshadowed collodion cannot be seen. Such results suggest that particles much smaller than the molecules of hæmocyanin can be recorded through the use of this replica technique.

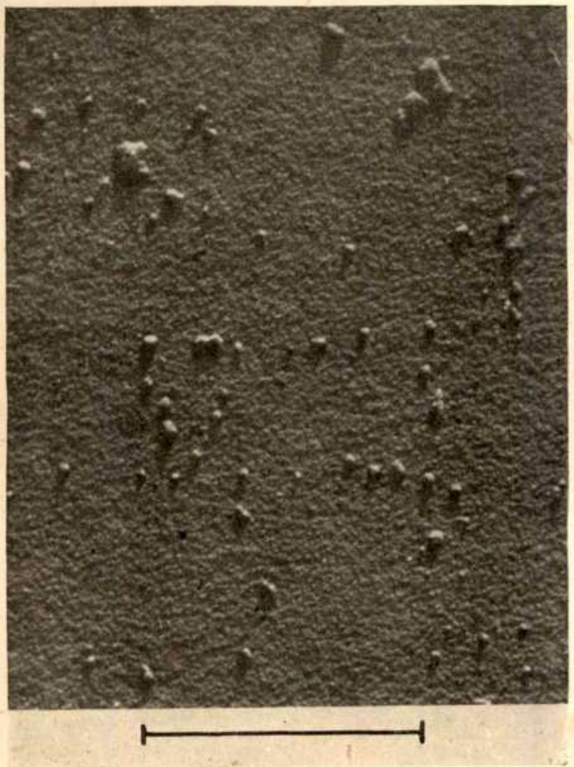

Fig. 2. A MICROGRAPH OF A MORE DILUTE HÆMOCYANIN SOLUTION SHADOWED BY THE OBLIQUE DEPOSITION OF 6–8 A. OF GOLD. RELATIVELY FEW HÆMOCYANIN PARTICLES, MOSTLY IN SMALL CLUSTERS, ARE DISTRIBUTED OVER THE PEBBLY COLLODION SUBSTRATE.

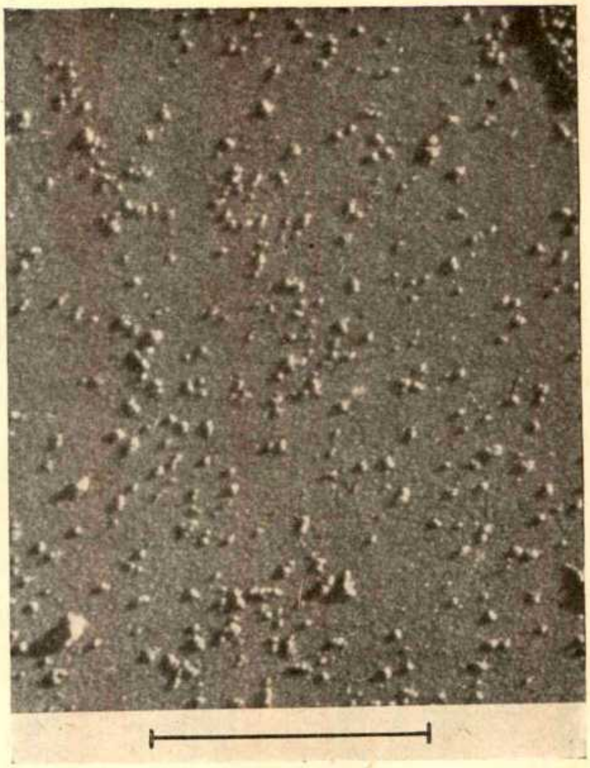

Fig. 3. A MICROGRAPH OF A GOLD REPLICA OF HÆMOCYANIN PARTICLES ON A POLISHED GLASS SUBSTRATE. A PORTION OF A LARGE HÆMOCYANIN CLUMP CAN BE SEEN AT THE TOP RIGHT-HAND CORNER. THE PARTICLES, AS WELL DEFINED AS IN FIG. 2, STAND OUT MORE CLEARLY ON THE SMOOTHER BACKGROUND.

The sizes of the individual particles of Figs. 2 and 3 have been compared with estimates of molecular size derived from rates of sedimentation in the analytical ultracentrifuge. The hæmocyanin from *Limulus* is not so satisfactory for this purpose as some other hæmocyanins would have been, had they been available, because its sedimentation diagram[7] shows evidence of four different particle sizes with sedimentation constants of 57, 35, 16 and 6 *s* units. Spherical molecules of proteins sedimenting at these rates may be expected to have diameters between something less than 100 A. and about 20 A. Diameters have been determined on four hundred particles in one photograph, care being taken to measure only those showing no evidence of clustering. These measurements of diameter were made at right angles to the direction of shadowing, since the size of particles should be little affected in this direction by the deposition of metal. When plotted they give an almost symmetrical Gaussian distribution curve that has its maximum at 165 A. and a width of 80 A. at half-height. Measurements on the unshadowed photographs[4] had led to a particle diameter of *c.* 200 A. We are not now in a position to discuss in detail either this lack of evidence of molecules corresponding to multiple sedimentation boundaries or the large spread in particle-size about its mean value. It seems probable that a factor in causing such a spread is shrinkage suffered during desiccation by these particles which, like most other protein molecules, are strongly hydrated in solution. In this connexion it will be noted that shadow lengths are in general less than ten times the particle-diameters, and that there is consequently a very considerable flattening of the particles considered as spheres.

SOME FACTORS CONCERNED IN THE PROCESS OF STARCH STORAGE IN THE BARLEY GRAIN

By H. K. ARCHBOLD

Research Institute of Plant Physiology, Imperial College of Science, London

CARBOHYDRATE synthesis in the barley plant displays two distinct phases, associated respectively with vegetative development and the succeeding period of ear development. The first phase is characterized by the irreversible synthesis of polysaccharides of the cellulose type based on C_6 and C_5 sugar and uronic acid units, which compounds account for 75 per cent of the carbon assimilated before the ear shoots. Starch appears only rarely, locally and in small amounts. The second phase is concerned almost exclusively with starch synthesis, and this substance, accumulated solely in the grain, may constitute 30 per cent of the total dry weight attained and more than half the dry matter of the ear.

The early view that sugar arising from the photosynthetic activity of the leaves was translocated up to the ear and there condensed to starch was superseded early in the present century by the notion that reserve materials were stored, mainly in the stem, during the vegetative stage of growth, and after the ear had shot formed its principal source of carbon. In 1920 Beaven[1] expressed the position as follows: "Some time before the grain is ripe the plant ceases to gain solid matter. Its last effort is to transfer its accumulated reserves into the grain, but all or nearly all the dry matter of the ear is first stored up by the leaves or stems of the plant. . . . It is mainly on the extent to which this uplift takes place that plenty or scarcity of the food of man depends."

The basis of this view was the recognition of the fact, pointed out by Dehérain and Dupont[2] in 1901, that during the period of active starch synthesis, the leaves of cereals were senescent and so unlikely to be capable of producing the requisite sugar by photosynthesis; but it overlooked their suggestion of an alternative assimilating surface together with their demonstration of the assimilating power of the stems. From this conception of migration as a distinct and important physiological process, Beaven termed the ratio of grain to total tops the 'migration ratio' and selected high-yielding varieties on this basis in the belief that high ratios implied efficient migration. Afterwards Engledow and Wadham[3], from thorough studies of the yielding power of cereals, concluded that only the 'migration ratio' appeared to hold any promise as an index of yielding power. There were at that time no adequate chemical data to lend quantitative support to this quite unequivocal hypothesis, but by 1924 Colin[4] and Belval[5] showed that sugar concentration in the cereal stem, chiefly sucrose and fructosan, increased to quite high levels prior to flowering, and afterwards declined as the grain filled These results were considered not only to support the migration theory but also to specify the principa migratory substances as the sugars of the stem; at the same time the notion was stressed that the upward movement was in some way initiated by the demands of the developing ear.

In the last decade two lines of work have led to a reconsideration of the position. Seasonal changes in dry weight of barley and wheat were studied concomitantly with sugar changes by Archbold[6] and Barnell[7,8]. Both groups of data suggested that the amount of sugar stored in the stems was insufficient as almost the sole source of carbohydrate for the ear. In the meantime, Boonstra[9] and Smith[10] had shown, by experiments with shaded wheat ears, that the ear itself is an important assimilating organ, an observation later extended to barley by Watson and Norman[11]. These experiments, besides establishing the assimilating function of the ear, weaken the simple assumption that increase in dry weight of the ear accompanying loss in weight of the stem necessarily denotes upward migration of previously stored material. It now seems likely that the earlier view is correct, and that starch synthesis proceeds simultaneously with the formation of its precursor by photosynthesis, storage of reserves during the vegetative stage of growth playing no essential part. Assimilation for this purpose is not, however, confined to the leaves, but is carried on in turn by all the green surfaces of the plant. A short account of the considerable body of evidence which has now accumulated supporting this view forms the subject of this article.

The first aim of the studies was to establish the part played in the nutrition of the ear by the immediate translocation of newly assimilated carbon and by the upward movement of temporarily stored products, including among the latter nitrogenous compounds. Analysis of some forty-eight samples of plants grown under a variety of manurial treatments established that there were no unidentified sources of possible migratory substances. The whole dry weight of leaves and stems was accounted for in the common groups, sugars, organic acids, proteins, cellulose polysaccharides and so on. Apart from the sugars, the organic acids formed the largest single fraction of the water-soluble material, and although not of importance in the present connexion there is no reason to suppose they are without metabolic significance; indeed, striking responses to manurial deficiencies have been established. A special search was made for sugar combined in forms other than those usually estimated, but only a small amount of 'glycoside' glucose liberated by N acid hydrolysis was found. This occurred mainly in the leaves and showed a downward drift with time, but since the maximum amount present was of the order only of 1 per cent of the dry weight of the mature ear, it can be dismissed as a possible reserve substance. Throughout a long series of experiments no evidence of significant loss of constituents of the water-soluble fraction of the dry weight other than sugar has been found; if anything, this group tends to increase a ttle in the stems rather than decrease as the ear develops. The whole relevant change in dry weight of the vegetative organs is therefore accounted for in terms of the losses of sugar and of the fraction insoluble in water and alcohol, namely, proteins and polysaccharides.

Having delimited the possible sources of supply for he ear to sugars, and to 'cellulose' and protein, it was possible to examine the total dry-weight changes by simply weighing the alcohol/water-insoluble fraction and estimating sugar in the extracting fluids. Proceeding along these lines, it was found by Archbold and Mukerjee[12] that at no time did the roots provide material for upward translocation. Root sugars were always extremely low (maximum 1 per cent of total plant sugar) and there was no evidence of polysaccharide breakdown in these organs. The roots may thus be safely disregarded. Major changes during ear development were therefore confined to the stems and leaves, and in these organs to the cellulose/protein fraction and the soluble sugars, both of which declined continuously from maxima reached at about the time of ear emergence. These losses, measured in four seasons, were equivalent to 8–18 per cent of the dry weight of the mature ear for sugars, and 1–10 per cent for the cellulose/protein groups, with averages of 12·5 per cent and 5 per cent respectively. Part of this latter loss will represent transferred nitrogen, and so is a maximum estimate of possible polysaccharide loss. If it be assumed that the whole of this loss from leaves and stems represents material moved into the ear, the maximum amount which can be supplied in this way is about 20 per cent, leaving at least 80 per cent to be supplied by assimilation proceeding simultaneously with ear growth. It must be concluded that the conception of migration as a distinct and important process initiated by the shooting of the ear is not well founded and that the ear differs in no essential way from the internodes of the stem as regards its development. Primary assimilate from the subtending leaf provides the carbon for the growth of each internode, any excess appearing as sugar; similarly the ear depends largely upon leaf assimilate for its early growth, but later stores the products of its own photosynthetic activity as starch. In spite, therefore, of the high concentrations of sugar reached in the barley stem (5–14 per cent according to nutritional conditions) the absolute amounts are not large relative to total ear weight, and the indications of the earlier experiments are borne out, that the stored sugar is at best only of secondary importance as a source of supply to the ear.

In order to investigate further the factors controlling sugar movement, a second series of experiments (Archbold[13], and Archbold and Datta[14]) was carried out, in which carbohydrate shortage was artificially induced in an attempt to divert to the ear both carbohydrates immediately formed by assimilation and those stored in the stem. For this purpose the three main centres of assimilation, namely, leaves, stems and ears, were in turn put out of action either by removal (leaves) or by shading of the organ (stems and ears). The treatments were carried out on one or more occasions during the four weeks prior to ear emergence, the period of rapid sugar accumulation in the stems, and again at about the time of completion of stem growth, contemporarily with the maximum stem sugar level. Defoliation three weeks or more before ear emergence was followed by an immediate fall in stem sugar, but after about seven days the level rose again slowly to a very much reduced maximum coincident in time with the maximum in control plants. Later defoliation resulted in a continuous fall in stem sugar; this treatment therefore prevents or much restricts accumulation of sugar in the stems, and at the same time stem growth, as measured by increase in the cellulose/protein fraction, is also restricted. Ears nevertheless continued to develop, attaining a final dry weight ranging, in several experiments spread over three seasons, from 0 to 25 per cent less than that of normal plants. Shading the stem two to four weeks before ear emergence resulted in a temporary check in stem sugar accumulation, which was afterwards resumed at the normal rate; stem growth was again restricted and the dry weight of the ear reduced by amounts up to 20 per cent, largely due to a reduced number of grains. Finally, early shading of the ear reduced only slightly the level of sugar in the stems and exerted negligible effects on its growth, while the dry weight of the ear was reduced by 30 per cent. Composition of the leaves was unaffected by either of the shading treatments, so that leaf sugar was not depleted to meet carbohydrate deficiency elsewhere, and accordingly it may be assumed that in these circumstances leaves continue to export the normal amount of sugars, and furthermore, that the leaves are the main source of the sugar normally accumulating in the stems. The time sequence of sugar change remained unaltered, so that the main effect of the checks on sugar accumulation in the stem was to lower the maximum attained; the reduction was large after defoliation, but only small after shading of stems or ears. In the subsequent phase of falling stem sugar the relative rates of sugar loss were either unaltered or slightly lowered in the treated plants, and approximately zero levels were always reached at the same time as in control plants. Depletion of the stem sugar was not therefore accelerated by the induced carbohydrate shortage, the rate of loss being apparently chiefly dependent upon the maxima reached and so upon sugar concentration. This conclusion is supported by the behaviour of earless tillers. If ears are removed during the phase of rising sugar content in the stem, additional accumulation occurs and concentrations up to 18 per cent may be reached. The maximum again coincides in time with that of control plants, and later sugar is lost at rates even greater than that in normal tillers, although no ear is present.

When defoliation and shading treatments were delayed until stem sugar had reached its maximum value, ears had emerged and attained about 40–50 per cent of the final dry-weight and, moreover, active starch synthesis was now in progress. At this stage treatments were without effect on the rate of sugar loss, nor was there any induced breakdown of polysaccharide to supply the ear, while only shading of the ear had large effects upon the ear itself. The reduction in ear dry-weight due to this late defoliation ranged only from 0 to 9 per cent, and due to stem shading was of the order of 5 per cent. The effect of ear shading, however, remained of the order of 30 per cent, equivalent to at least half the total amount of starch, from which it seems that after ear emergence the ear may be altogether autonomous in respect of starch synthesis.

Taken together, this group of experiments indicates that only very limited diversion to the ear of sugar newly assimilated in the leaves is possible, as represented by the slightly reduced maxima attained in the stems after early shading of stems or ears; there is no evidence of diversion of previously stored sugar, or of induced polysaccharide breakdown in response to the carbohydrate shortage supposedly arising as a result of treatment. The sugar accumulating in the stems is shown by the defoliation and stem shading experiments to originate in the leaves; but the presence of excess sugar is not in itself sufficient to ensure continued growth, since accumulation proceeds in plants with shaded stems or ears accompanied by restriction of ear growth and in the former case of stem growth as well. Only after early defoliation did there appear to be a condition of true carbohydrate shortage. The complex mechanisms controlling starch and cellulose synthesis do not therefore respond directly to the supply of carbohydrate but require that the plant shall be intact and in the light, and it seems that under normal environmental conditions, as well as those imposed in these experiments, sugar accumulation results from over-production in relation to the capacity of these mechanisms rather than as a necessary reserve substance. The accumulated sugar is not, however, in a static condition, and the levels are presumably only maintained by a process of continuous replacement, since arresting the supply of fresh assimilate either by defoliation or by exclusion of carbon dioxide from the surrounding atmosphere leads to an immediate fall in sugar-level.

The absence of effect upon stem sugar losses, when assimilation was partially prevented at the time of maximum stem sugar, is particularly striking and suggests that the role of stored sugar as a reserve for the ear is very questionable. It has been shown that this sugar cannot form a large part of the carbon supply to the ear, and the continued development of ears in defoliated plants, where this store of sugar is virtually absent, shows that it is not essential to later stages of ear growth. Finally, the high rate of loss of sugar from stems deprived of ears shows that the ear is not concerned in the control of this process. The question then arises as to whether in fact this stem sugar is not lost as part of the normal senescent drift of the stem itself rather than by upward translocation to the ear. The distribution of sugar between the several internodes lends some weight to this view. Each internode appears to behave as an independent unit, depending for its sugar supply upon the attached leaf, a fall in sugar ensuing when the leaf is no longer functional, and moreover the evidence suggests that there is no rapid interchange between one internode and another.

It is recognized that conclusive evidence of the precise fate of sugar in the cereal stem is not yet forthcoming, and the view that it is not lost by upward translocation requires substantiation. Alternative possibilities would appear to be conversion *in situ* to other compounds or loss as carbon dioxide. At present the former possibility is quite unexplored, but a start has been made in the study of the respiration of the stem. Carbon dioxide output during the hours of darkness and at prevailing night temperatures has been measured for whole tillers, and for defoliated and earless stems, during the phase of falling stem sugar. On the assumption that sugar loss is continuous throughout the twenty-four hours the average rate of loss (0·35 mgm. per gm. dry weight per hour) in whole tillers showed good agreement with the respiration rate (0·32 mgm. per gn dry weight per hour, calculated as hexose) observe for the dark hours. If, therefore, the day-tim respiration is of the same order as that at night an the carbon dioxide reassimilated during the da appears in a form in which it can be synthesized t starch, it might be concluded that all the sugar los is accounted for by oxidation to carbon dioxide However, the agreement for the stems alone was les good, and here the rate of sugar loss (0·45 mgm. pe gm. dry weight per hour) was apparently higher tha the equivalent carbon dioxide output (0·25 mgm. pe gm. dry weight per hour). Moreover, not only ar essential respiration requirements met in defoliate stems with very low sugar contents; but also in stem of nitrogen-deficient plants, where respiration rate i presumably low, rate of sugar loss is high owing tc the high sugar-levels induced by this deficiency More data are therefore required before a definitive estimate of the proportion of stem sugar lost in respiration can be made, and it can only be suggested that perhaps half the sugar may be accounted for in this way.

Failure to induce sugar movement by partial prevention of assimilation, together with the clear indication that in plants with shaded stems or ears factors other than carbohydrate deficiency were operative in controlling sugar utilization, led to an attempt by Archbold and Datta[15] to influence sugar movement by exploiting the known effects of nitrogen deficiency on sugar content. Nitrate was supplied to the plant at the time when sugar was accumulating rapidly in the stem and also at the time of the sugar maximum. On both occasions uptake was rapid for about a fortnight and the nitrogen content of tillers already present was more than doubled, while at the same time new tillers arose. The plants developed the deep blue-green colour characteristic of high nitrogen status and remained green for some time longer than controls. Active reduction of nitrate took place immediately and at first the additional nitrogen was found distributed between all the organs, about 30 per cent going to the leaves and 40 per cent to the stems after the earlier of the two applications, but by harvest all had been transferred to the ears. Concurrently with this rapid nitrogen uptake, sugar accumulation in the stems was restricted, presumably by preferential utilization of the leaf assimilate for union with the reduced nitrate. There followed a slow rise of stem sugar to a lower maximum than in the control plants, and still later a slow rate of loss in the senescent phase of the stem. This course of sugar change differs from that found after early defoliation only in that the restriction of the sugar accumulation is not so great. When the addition of nitrate was delayed until sugar was maximal in the stem, the onset of sugar loss was actually also delayed, although 80 per cent of the nitrogen taken up appeared at once in the stems and ears. At this stage, therefore, addition of nitrate prolonged the time during which the stems remained green and at the same time maintained a high sugar-level, again indicating that sugar loss from the stem is associated with senescence rather than with ear growth. At both stages, synthesis of nitrogenous compounds was apparently effected at the expense of newly assimilated carbon.

Preliminary attempts to determine whether such new assimilate was essential for elaboration of the nitrogen have only served to stress the complexity of the problem. By supplying nitrate to detached llers in the light either in air or in a carbon dioxide-ee atmosphere it was found that sugar loss was ccelerated in the presence of the added nitrogen, hether or not carbon dioxide was excluded. The dditional sugar loss, however, bore no obvious elation to the amount of nitrate reduced, and indeed n one case, where the initial nitrogen level of the ample was high, no reduction of the nitrate taken p could be observed, although the high rate of sugar oss still occurred. Nevertheless, the experiments with dded nitrogen fall into line with those dealing with arbohydrate shortage in that accumulation of stem ugar in intact plants was inhibited by the treatment, ut rate of sugar loss was not accelerated. Numerous well-known experiments with detached leaves have hown that stable sugars can be taken up and converted to starch, or lead to production of nitrogenous compounds when supplied along with a suitable source of nitrogen. The failure of the barley plant to utilize stored sugar in this way may therefore be due o the location of the sugar rather than its chemical form, and the preferential use of primary assimilate arise from the ease with which it can be brought into association with the appropriate enzyme mechanisms. At present it is not known whether the starch-forming enzymes occur exclusively in the grain, but in the meantime formulation of schemes whereby fructosans or pentosans might be converted to starch appear superfluous, since evidence of upward translocation of the former is lacking, and the evidence points to an irreversible synthesis of the polysaccharides from which the latter might be derived. Rather a single starch precursor may be postulated largely produced *in situ* in the ears and possibly identical with the translocatory substance (sugar ?).

Since the carbon used for ear development and especially for starch synthesis derives principally, if not entirely, from current assimilation, the available evidence regarding the functional importance of the several plant organs in this respect may be summarized. From a number of defoliation experiments it is estimated that, after ear emergence, the leaves supply not more than 10 per cent of the final dry weight of the ear compared with a contribution of 30 per cent by the ears themselves. Before ear emergence the leaves may contribute a further 15 per cent, mainly leading to polysaccharide and protein synthesis. There remains the rather large amount of 45 per cent attributable by difference to stems and sheaths, of which somewhat less than half is contributed before emergence of the ear. Attempts to confirm this estimate by experiments in which stems were shaded or in which only stems were left exposed to light led to conflicting results owing to the different effects of treatment other than the prevention of assimilation. Shading the stem at the time of ear emergence had little effect on the final dry weight of the ear, indicating a small assimilatory capacity at this stage, a view supported by the failure of stems deprived of ears and leaves to accumulate sugar as compared with those from which only ears were removed. When stems alone were left exposed to light, however, a higher estimate of the apparent assimilatory capacity was obtained. As a rough approximation perhaps half the material of the ear accumulated before emergence may be attributed to activity of the leaves and half to the stems and sheaths, of which latter half a large proportion is probably derived from the flag leaf-sheath[13]. The rapid senescence of the leaves after ear emergence suggests that the estimate of 10 per cent or less for their contribution during the period of active starch synthesis is probably correct, leaving the mode of division of the remaining 40 per cent as between stems and ears uncertain. The data thus confirm the view that leaves are relatively unimportant as regards starch synthesis, and make their essential contribution in the period before ear emergence. If the discrepancy between the estimates of the stem contribution is in part due to under-estimation of the contribution of the ear itself, this organ may prove to be almost wholly responsible for the immediate starch precursor.

The experiments summarized here, dealing with the sugars of the barley plant, cast doubt upon the hypothesis that the stored sugar of the stem is a reserve for maintaining the growth and development of the fruit. If the alternative view be accepted that this sugar is lost as part of the inevitable senescence of the stem itself, then the function of accumulations of sugar not only in other monocotyledonous stems, for example, the sugar cane, but also of other types of storage organ may need reconsideration in this light. In storage roots such as carrot or sugar beet it is well known that the separated crown can produce a flowering stem though deprived of the bulk of the stored carbohydrate; similarly, in tubers such as artichoke and potato, the so-called reserves of inulin and starch are not essential to successful regeneration. Thus, while it is manifest that some part of the 'carbon' of the storage organs must undergo metabolic changes leading to shoot formation, the amount involved is probably small in relation to the total carbohydrate reserve, and the same general interpretation is possible for these types of sugar accumulation as for the barley stem; namely, that sugar is produced in excess of immediate growth requirements and becomes isolated in parenchymatous tissue, from which it disappears slowly with the senescence of the 'storage' organ. These two types of sugar storage would then fall into line, as regards absence of essential function in subsequent growth, with the sugar of the fleshy fruits, which cannot be regarded as a substrate for future growth. The resulting unification of the conceptions of the status of these three types of sugar accumulation emphasizes the view that sugar concentration of itself plays no part in initiating plant syntheses, but rather that stable sugar arises when assimilatory capacity is in excess of that for utilization. The necessity for a better understanding of the factors, of which nitrogen supply is of first importance, controlling sugar utilization is obvious.

If any function is to be attributed to the sugar in such organs as the shooting stem of the cereal it may perhaps be concerned with maintenance of turgor in the rapidly elongating cells, but this is frankly speculative, and at present without experimental verification.

OBITUARIES

Prof. Leif Tronstad, O.B.E.

The death of L. H. L. Tronstad on active service in Norway, while leading a daring operation in March 1945, has deprived his country of one of its most outstanding men of science, and his collaborators in all parts of the world of a valued friend.

Leif Hans Larsen Tronstad was born in 1903 at Baerum, near Oslo; his father, a farmer, died the same year. He studied chemistry in the Oslo Technical School and the Norwegian Technical University at Trondheim, obtaining brilliant successes despite the fact that he was at the same time working as a teacher and in support of his widowed mother and sister. His first important research was carried out at Berlin, during 1928–29, in Prof. Freundlich's laboratory. A qualitative method of detecting thin oxide films on metals, based on changes in the ellipticity of polarized light, had already been worked out by Freundlich, Patscheke and Zocher. Tronstad succeeded in developing the method to give quantitative measurements of thickness, and showed that, when iron was made passive by anodic treatment, the film thickness increased, while during cathodic activation the thickness diminished. This work not only supplied valuable information as to the causes of passivity, but also suggested a new method of ascertaining the thickness of invisible films, and the nature of the film substance.

After further work on films resulting from electrochemical treatment, carried out in Prof. Benedick's laboratory at the Metallografiska Institutet, Stockholm, for which he received his doctorate at Trondheim, Tronstad proceeded in 1931 to the University of Cambridge. There he improved the method further, testing its accuracy by the study of monolayers of fatty acids, the thickness of which could be measured in other ways; part of this work was carried out in collaboration with C. G. V. Feachem.

Later Tronstad returned to Norway and was elected in 1934 to a temporary professorship in technical inorganic chemistry at the Norges Tekniske Högskole; this chair was made permanent in 1936. He was one of the youngest professors in the country, popular alike with students and colleagues, and enjoyed the reputation of being a first-class teacher. At this stage he was joined by A. B. Winterbottom, and the polarized light method of studying films on metals was developed further. Although not well known to-day, its value is likely to become increasingly appreciated as time passes, especially as it can be employed for just that range of thickness where alternative methods are least useful. Moreover, the method can be used for the continuous study of a film *in situ* during its growth in almost any environment.

Tronstad's interests were by no means confined to the study of films. He played a leading part in the organization of the Rjukan hydrogen plant of Norsk Hydro, for the large-scale separation of heavy water, large quantities of which were supplied for scientific research in Great Britain. Determinations of the physical constants of several deuterium derivatives were made by Tronstad and his associates at Trondheim and Rjukan. Tronstad's electrochemical knowledge was of the greatest value to the Norwegian industries, especially those connected with steel, ferro-alloys, nitrogen, refractories and aluminium; he also carried out researches on the effect of minor elements on the corrosion of aluminium and iro
His published scientific papers number about sixt

Tronstad was greatly attached to Great Britai
where he had many friends. His modesty, sincer
and cheerful good-humour were appreciated by
who met him. He had numerous interests outsi
science; for example, he was a fine athlete, being
his student days a member of the relay team whic
set up a Norwegian record for the 4 × 400 metr
distance; he was also a lover of natural beauty, a
took pride in Norwegian country folk and customs.

During the War, Tronstad was engaged in dari
and dangerous work for his country, which led, on t
eve of victory, to his death in action. Details of h
many-sided war activities must not be given; b
it may perhaps be stated that the results achieve
which demanded the highest courage, organiz
capacity and scientific skill, contributed directly
the speedy victory of the Allied Nations, besid
saving the region which came to be known as 'Souther
England' from an even longer and more severe orde
than it actually endured. He received the Order
the British Empire for his outstanding services.

We would like to thank Mr. A. B. Winterbotto
and Capt. J. H. Reimers, as well as the Roy
Norwegian Government Information Office, for kin
assistance on many points.

Don Ignacio Bolivar y Urrutia

With the death in Mexico on November 20, 1944 of Don Ignacio Bolivar y Urrutia, the world ha
lost one of the most eminent Spanish naturalists of
generation belonging as much to the last century a
to the present. Ignacio Bolivar was born on November 9, 1850, a member of a noble and ancient family. Although interested from an early age in natural history, young Bolivar had to take up law studies, since his parents hoped that these would provide him with a better livelihood; but he took a degree in natural sciences as well. Before he was twenty, Bolivar became an ardent member of a small but very active group of young Madrid entomologists, and spent much of his free time in exploring the Spanish fauna.

When the Sociedad Espanola de Historia Natural was founded in 1871, Bolivar became its vice-secretary, and in 1872 his first scientific paper was published by the Society. In 1875 he joined the staff of the Madrid Natural History Museum as an assistant in the Zoology Department, specializing in entomology. The whole subsequent career of Bolivar was passed in the Museum, of which he eventually became director, and which grew from a small establishment to an imposing scientific institution and a centre of research. In 1877, Bolivar was also appointed to a chair in the University of Madrid, where he continued lecturing in zoology until 1922, and his combined work in the Museum and the University served to make him one of the leading naturalists in Spain and a teacher of more than one generation of Spanish biologists.

Although primarily a taxonomist himself, Bolivar was always a champion of the study of living organisms, and it was due to his efforts that a marine biological station was established in Santander, while the Estacion Alpina de Biologia in Sierra de Guadarrama, also founded by him, was a somewhat unique ntre where Spanish and foreign biologists were able find modest accommodation and good laboratory cilities amidst unspoilt Nature. This long and utful activity was rudely interrupted when at the e of ninety Bolivar became an exile, followed by a oup of his colleagues. It was characteristic of nacio Bolivar and his younger followers that in exico they should take a most active part in the ientific life of the country of their adoption, and are ntributing greatly to its scientific exploration. A onthly journal, *Ciencia*, launched by them, rapidly ecame a widely known medium of biological knowdge in Latin America.

Although Bolivar published some papers on the emiptera, on other insect orders and on Crustacea, e specialized from his earliest days on the systematics f the Orthoptera, a group particularly well epresented on the Iberian peninsula, where it inludes a high proportion of endemic genera and pecies. The total number of papers published by olivar was about two hundred and thirty, and he escribed more than two hundred new genera and bout a thousand species of Orthoptera. His work on his order partly coincided in time with that of runner, Saussure, Pictet and Redtenbacher, and he s to be included with them as a creator of the modern ystem of Orthoptera.

While a great deal of Bolivar's work was purely lescriptive, we owe to him also a series of revisions nd monographs, and his works on the Tetrigidæ, Pamphaginæ, Pyrgomorphinæ, Truxalinæ and Ephippigerinæ, still remain indispensable for a taxonomist. From the faunistic point of view his main contribution was, of course, to the study of the Iberian fauna, but he ranged widely in his work, from India to the Seychelles and from the Congo, Angola and Spanish Guinea to South America.

Most present-day orthopterists regard Ignacio Bolivar as their master and it was a great and touching occasion when in 1935, during the Sixth International Entomological Congress at Madrid, a group of some fifteen orthopterists of various nationalities gathered round him for a 'family' celebration. For those who knew Don Ignacio personally, it was impossible not to fall under the spell of his vital personality, full of noble and simple charm. His energy was prodigious, and I shall never forget an excursion to the highest peak of Sierra de Guadarrama, when Don Ignacio, then well over seventy years old, led the way on foot for several hours.

The value of Bolivar's work was recognized by the Entomological Societies of London, Belgium and Prague, which elected him honorary fellow, while the Zoological Society of London included him among its twenty-five foreign members. Among many other academic distinctions, he was a doctor *honoris causa* of the University of Pittsburgh. B. P. UVAROV.

Dr. G. C. Robson

GUY COLBORN ROBSON, whose death occurred on May 17, 1945, after a long illness, was born at South Woodford, Essex, on February 11, 1888. He obtained a Classical Scholarship at New College, Oxford, where he entered into residence in 1906. He took Classical Moderations, and then changed over to science, reading for honours in zoology, in which he obtained a first class, and afterwards spent a year in Naples, where he studied the fat-metabolism of crabs infested with *Sacculina*. He joined the staff of the British Museum Natural History in 1913 and was put to work on the Mollusca under Edgar Smith. He became a well-known authority on this group and devoted much attention to their anatomy, as well as the 'conchology' on which earlier classifications were mainly based. He published numerous papers, mainly on the Cephalopoda, including perhaps his most important work, a monograph on the Octopoda, published by the British Museum in two volumes (1929 and 1932). He also studied the biology of *Paludestrina jenkinsi*, a parthenogenetic freshwater snail introduced into Britain some time during the eighties of last century, and now widely distributed throughout Britain.

Robson was attracted to zoology from the philosophical side and it is doubtful whether he was entirely happy in his museum life. His intellectual interests were many and varied—artistic, literary, sociological, philosophical. The latter bent is best shown in his two books, "The Species Problem" (1928) and (jointly with O. W. Richards) "The Variation of Animals and Plants in Nature" (1936). His artistic gifts are evident in the illustrations to his papers and also in his water-colours.

During the War of 1914–18, he served first with the Red Cross and then with the Royal Garrison Artillery and was attached to a coast defence unit. He was bombed during an air attack, and, after spending a year in hospital suffering from shell-shock, was invalided out of the service. He returned to the British Museum, where he spent some of the most productive years of his life and became a deputy keeper. Unfortunately, he never seemed to have recovered fully from his illness, and in 1935 had another nervous breakdown necessitating his resignation from the Museum. He spent the last few years of his life in retirement. E. HINDLE.

Some Czechoslovak Men of Science

NEWS has just reached London that several more Czechoslovak professors, displaced when the Germans closed the universities of that country in 1939, have died in concentration camps. They include Prof. V. Dolejšek, Prof. F. Ulrich and Prof. J. Štorkán. Prof. F. Slavík, a mineralogist well known in Britain and now sixty-nine years old, was rescued from Buchenwald by the Allies just in time, and has now been able to travel to Prague. The fate of Prof. F. Záviška, the physicist, is unknown; he has not yet been traced.

It is now known that Prof. A. Šimek, whose death has already been referred to in *Nature* (**152**, 69; 1943), was executed at Mauthausen concentration camp.

Prof. Dolejšek was a distinguished physicist who worked for a time with Prof. Manne Siegbahn in Uppsala. Some of his work on X-ray spectra was first published in *Nature*, and he is perhaps best known for his discovery of the N-series of X-ray lines. He died at the Terezín camp in January last.

Prof. F. Ulrich had carried out many mineralogical investigations of considerable local interest and had made important petrographic and geological studies. He was also the author of several authoritative treatises on geology and had been elected honorary foreign member of numerous European scientific societies.

Prof. Štorkán had a distinguished career as a zoologist and was an authority on the Central European fauna. He was only fifty-four at the time of his death. G. DRUCE.

NEWS and VIEWS

Prof. G. H. Hardy, F.R.S.

THE appointment earlier this year of Prof. L. J. Mordell to the Sadleirian chair of pure mathematics in the University of Cambridge is a reminder that Prof. G. H. Hardy retired from the Sadleirian chair so long ago as 1942. Throughout his long career as lecturer at Trinity College, Cambridge, during 1906–19, as Savilian professor of geometry at Oxford during 1919–31, and as Sadleirian professor of pure mathematics at Cambridge from 1931 until his retirement in 1942, Prof. Hardy has been a leader of mathematical thought. Forty years ago, mathematical analysis was neglected in England. To-day the English school of analysts commands respect and admiration throughout the world. This development is due almost entirely to Hardy, by the direct inspiration of his own teaching and personality, and through the medium of successive generations of his pupils. An important part was played, particularly in the early stages, by his stimulating book "A Course of Pure Mathematics", first published in 1908 and now in its ninth edition. But it is not possible in this short note to attempt any proper appreciation of the great volume of Hardy's original work, or to recount the imposing list of his collaborators. Chief among these is his former pupil, J. E. Littlewood, who has been a constant partner since about 1912.

The headings under which Hardy's work may be broadly classified (theory of series, theory of functions, Diophantine approximation, inequalities, analytical theory of numbers, Fourier analysis) are closely related, and many of the interrelations can be traced to Hardy's own influence. Thus the impressive body of "Tauberian" theory, with which Hardy and his followers have enriched the theory of series, finds some of its principal motives and applications in the theory of numbers. Again, the researches of Hardy and Littlewood on Diophantine approximation involved a profound study of certain power series near the circle of convergence, and this was no doubt the germ of the famous Hardy-Littlewood-Ramanujan analytical method in the additive theory of numbers, one of the greatest and most fruitful mathematical discoveries of this century. The name Ramanujan recalls what Hardy has described as the one romantic incident in his life—his association with the self-taught Indian mathematician who was to achieve world-wide fame under his guidance. This fascinating story has been told by Hardy himself. It is mentioned here as an example of what Hardy's pupils, one and all, owe to him, perhaps in more orthodox and more prosaic circumstances, in personal interest and sympathetic encouragement of their early efforts—a debt more fully appreciated in later life with the coming of mathematical independence and maturity.

Many honours have been conferred upon Hardy. He became a fellow of the Royal Society in 1910, and was awarded a Royal Medal in 1920 and the Sylvester Medal in 1940. In 1933 he received the Chauvenet Prize of the American Mathematical Association. For forty years he has been a tower of strength to the London Mathematical Society as member of its council, as secretary, and as president. He was awarded the de Morgan Medal of the Society in 1929. Hardy is the author or joint author of several books, all written in the vivid style familiar to readers of his original papers. "A Mathematician's Apology", published in 1940, was received with enthusiasm by th wider public to which it was addressed. Hardy technical writings, as well as his provocative pr nouncements on philosophy and pedagogy, are ofte enlivened by apt illustrations from cricket or othe games, sometimes to the bewilderment of foreig readers.

Anthropology in the University of London: Prof. C. Daryll Ford

THE provision for the study and teaching anthropology in London is being strengthened by th revival of the department in University College whic has been partly suspended during the War. Pro C. Daryll Forde has been appointed to the chair, an he will take up his duties at the opening of the ne session. Prof. Forde first went to University College i 1919, and was there, as student and later as a junio member of staff, until 1928. He worked under Prof Lyde and Elliot Smith in the period in which th latter gave so strong a stimulus to anthropologica studies by the development of his theories on th diffusion of culture. From there he went, with Commonwealth fellowship, to California, and spen two years on studies of the Pueblo Amerindians o the south-western United States and norther Mexico. In 1930 he was appointed Gregynog professor of geography and anthropology in the University of Wales, at University College, Aberystwyth.

After the publication of the results of his fieldwork in America, Prof. Forde became interested in Africa. He has carried out field work in West Africa, where he was caught by the outbreak of war in 1939. Since then he has served in the Foreign Office Research Department, as a member of the Nuffield colonial research team, and for the past year as director of the International African Institute. He has published many papers, and his book "Habitat, Economy and Society" is a well-known exposition of work done in the study of primitive societies. These, and a forthcoming book on native economies in Nigeria, indicate his range of work. He is essentially a field anthropologist, holding that such study of simpler societies can lead to a real understanding of the more primitive peoples, and contribute towards a better knowledge of more complex human societies, such as our own.

Marine Biological Association Laboratory, Plymouth: Mr. F. S. Russell, D.S.C., D.F.C., F.R.S.

THE Council of the Marine Biological Association has appointed Mr. F. S. Russell to be director of the Association's Laboratory at Plymouth in succession to the late Dr. Stanley Kemp. Mr. Russell has been a member of the staff of the Association since 1921 and has played a very important part in the work of the Plymouth Laboratory. His work has thrown much light on the factors which control the distribution of planktonic organisms, and on the relationship of these organisms to more strictly fishery problems. Mr. Russell is at present serving in the Royal Air Force and holds the rank of wing commander.

Mrs. Seán T. O'Kelly

MRS. SEÁN T. O'KELLY, wife of the newly elected president of Ireland, is well known as Miss Phyllis Ryan, public analyst, in Dublin. She studied chemistry under the late Prof. Hugh Ryan at University College, Dublin, graduating in 1916, and obtaining e M.Sc. degree by research in 1917. She collaborated th Prof. Ryan in a number of investigations, in- iding one on the action of nitrous and nitric acids diphenylamine carried out with the co-operation Nobels, Ltd. Later, she set up practice as a con- lting chemist in Dublin, and became public analyst r twelve Irish county councils. In this connexion, is of interest to note that all the members of her boratory staff are women graduate chemists. She s concerned herself vigorously with the organization the chemical profession in Ireland and is a past esident of the Irish Chemical Association. Her new here of activity will, unfortunately, prevent her om continuing to take an active part in the work her profession.

ducational Director of the British Council : Dr. A. E. Morgan

Dr. A. E. Morgan has been appointed educational irector of the British Council and will take up his uties early next month. The post was formerly eld by Prof. B. Ifor Evans, who resigned it on ppointment as principal of Queen Mary College bout a year ago but has continued to assist the ouncil in an advisory capacity. Dr. Morgan, a ative of Bristol, was educated at the then Univer- ty College there, and at Trinity College, Dublin. Ie became lecturer in, and then professor of, English anguage and literature in the University College, xeter, and later occupied a similar chair in the niversity of Sheffield. In 1926 he was appointed rincipal of University College, Hull; and during 1935–37 he was principal and vice-chancellor of McGill University, Montreal. Dr. Morgan became hief special officer for national service, Ministry of Labour, in 1939, and was thereafter a district commissioner for the Special Areas (Durham and Tyneside), and regional information officer at Newcastle-on-Tyne. Since 1941, he has been assistant secretary, Ministry of Labour. The period for which Mr. H. Orton, the acting educational director of the British Council, was seconded to the Council from the University of Sheffield ends on August 31, and he will then resume his duties as head of the Department of English Language at Sheffield.

The R. W. Paul Instrument Fund

The R. W. Paul Instrument Fund was established by a trust created under the will of Mr. R. W. Paul, who died in March 1943. The income from the fund will be administered by a committee composed of representatives of the Royal Society, the Physical Society, the Institute of Physics and the Institution of Electrical Engineers. The committee will consider and adjudicate upon applications which may be submitted for financial assistance by means of grants for the following purposes : (*a*) for the design, construction and maintenance of novel and improved types of physical instruments and apparatus for investigations in pure and applied physical science, particularly in cases where a relatively large expenditure may be justified on experimental apparatus. (*b*) For the assistance of research by provision of equipment, building facilities or financial or other aid in such manner as the committee may determine in each case. Grants from the fund shall not be used to relieve expenditure in any establishment controlled by the Government, or to relieve any university or other educational establishment of its normal financial obligations. When an application is favourably regarded by the committee, an assessor will be appointed to advise in detail on the merits of the application, the feasibility of producing the desired result by means of the proposed instrument or apparatus, the urgency of the need for it and the probable cost of execution of the work.

After a grant has been made, the assessor will report to the committee not less than once every three months on the progress of the work. He may in his discretion recommend additional grants for running and maintenance costs and salaries for the time being of investigators and assistants engaged in a particular investigation, provided that no research fellowship or research scholarship is thus created. The committee will decide the ultimate destination and ownership of all instruments and apparatus produced by means of grants from the fund. Any invention or improvement in existing inventions made by a grantee must be communicated forthwith to the committee, and no grantee may apply for, or obtain, patent rights for such invention without the previous sanction in writing of the committee. Applications may be submitted by any worker or group of workers in Great Britain. Applicants must be British subjects and their qualification in physical research must be supported by the signed recommendations of not less than two of the following persons : (i) president of the Royal Society (if a physicist), or alternatively, the secretary of the Royal Society dealing with physical subjects ; (ii) president of the Physical Society ; (iii) president of the Institute of Physics ; (iv) president of the Institution of Electrical Engineers. Applications should be addressed to the Assistant Secretary of the Royal Society, Burlington House, London, W.1.

Industrial Research Committee of the Federation of British Industries

At a recent meeting of the Grand Council of the Federation of British Industries, it was announced that Mr. B. J. A. Bard has been appointed head of the F.B.I. Research Secretariat and secretary of the F.B.I. Industrial Research Committee. Mr. Bard carried out fuel research under the late Prof. W. A. Bone in the Chemical Technology Department of the Imperial College of Science and Technology, and then read for the Bar ; he practised at the Bar until the outbreak of war, after which he worked first with the Coal Commission and, later, on various industrial production and research problems at the Ministries of Supply and Aircraft Production. The duties and functions of the research secretariat will include the encouragement and fostering of industrial and national interest in research, maintaining contact with all industrial research organizations, and providing a service whereby advice, assistance and information can be obtained and contacts made. Close touch is being maintained with the Department of Scientific and Industrial Research, which is represented on the F.B.I. Industrial Research Committee. A first task will be the organization of a survey of existing research facilities in Britain. Another immediate plan of the Industrial Research Committee is a proposal for a two-day conference, to be held in London in the autumn, of those who are organizing or conducting research in industry, in order that they may present their views and give the results of their experience to industry.

The Industrial Research Committee of the Federation of British Industries is constituted as follows : Sir William Larke (*chairman*), Dr. S. B. Bagley, Sir

Peter Bennett, Mr. W. Bond, Mr. O. F. Brown, Dr. W. T. K. Braunholtz, Dr. P. Dunsheath, Mr. T. A. Fairclough, Dr. W. H. Glover, Dr. W. T. Griffiths, Mr. A. L. Hetherington, Lord Melchett, Mr. R. O'F. Oakley, Dr. C. C. Paterson, Sir Robert Pickard, Mr. R. K. Sanders, Dr. R. E. Slade, Sir Frank Smith, Mr. S. K. Thornley, Mr. B. J. A. Bard (secretary to the Committee and head of the F.B.I. Industrial Research Secretariat).

International Collaboration

THE publication as a "Penguin Special" (price 9*d.*) of E. R. Stettinius' "Lend-Lease: Weapon for Victory" shortly after its original publication as a substantial work of 358 pages (New York: The Macmillan Company; London: Macmillan and Co., Ltd.) is a real service to Anglo-American understanding. Intended originally to facilitate the understanding in the United States of the Lend-Lease Act, it should contribute equally in Britain to the same end. This is important, because, if the new lend-lease agreement with the United States announced in November by the Prime Minister is to be fully understood, it must be remembered that the Lend-Lease Act is for the defence of the United States, and is strictly limited to what is necessary for the effective prosecution of the War by the United States and its Allies. The picture which Mr. Stettinius here paints of the way in which Lend-Lease developed and of the magnitude of the contribution which has been made to victory in Europe in this way is most impressive in its demonstration of the possibilities of collaboration between the United Nations and of the advantages which all might reap from the pooling of economic resources in facing the tasks and problems of peace. At a time when the organization of world order is receiving close attention, it is well that there should be made so widely available such an admirable account of one great experiment in international collaboration which has played a large part in bringing the war in Europe to a successful conclusion. The principle of mutual aid embodied in the Lend-Lease Act and agreements will not come to an end when the war with Japan ends: to it we must also look for the strength to build a world in which freedom and opportunity are secure for all.

British Grassland Society

AT the Fourth International Grassland Congress held in Great Britain in 1937, a group of grassland specialists met to consider the advisability of forming a society in the United Kingdom to promote the study of grassland husbandry. The outbreak of war prevented further progress with the scheme, but in November 1944 a group interested in grassland research met to discuss the foundation of a British Grassland Society, the activities of which would be field tours, discussions and the publication of a journal. The Society was formed early in 1945 and the first meeting was held at Stratford-on-Avon during June 20–22. About one hundred and fifty members attended. At the opening general meeting the following committee and officers were elected for 1945: *President*, Sir R. George Stapledon; *Vice-President*, Dr. Wm. Davies; *Committee*, J. H. Faulder, H. J. Gill, W. D. Hay, F. R. Horne, Prof. T. J. Jenkin, M. G. Jones, Prof. S. J. Watson; *Secretary*, Dr. R. O. Whyte; *Treasurer*, P. A. Linehan; *Editor*, Dr. H. I. Moore. The office of the Secretary is at the Agricultural Research Building, Aberystwyth. It w agreed at this meeting that membership should confined in the meantime to scientific and technic officers of Ministries, research institutes, war ag cultural executive committees and similar bodi Specialists in countries other than Great Britain c become members.

During the meeting, members visited the Gras land Improvement Station at Drayton, its form substation at Colesbourne in the Cotswolds ar representative grassland areas in Leicestershire. Drayton, herbage crops in seed production and le of different age, history, seeds mixtures and seedi rates were inspected. An interesting feature of t work at Drayton is the increasing emphasis which being placed on the interpretation of sward improv ment through the animal rather than by means botanical or chemical analyses alone; live-weig production trials accompanied the experiments. Colesbourne there were fertilizer trials accompanyin the establishment of leys and the seed productio of various forage crops. Visitors were impressed the productivity obtained from this thin Cotswol soil which only three years ago was derelict turf an dense thorn bush. Those from the north were pa ticularly interested in the crops of sainfoin. In tour through Leicestershire members inspected trial of cocksfoot, perennial ryegrass and other grasse conducted jointly by the Royal Agricultural Societ of England and the Leicestershire War Agricultura Executive Committee at Dunton Bassett and Thorp Langton. They saw the trial now in progress on the famous Mill Field at Medbourne to compare bee production on an old pasture (about one hundred an fifty years old) with that on a new ley in an adjacent field. Members also inspected ley farming and a gras and grain drying plant at Skeffington. Future plans of the Society will be decided shortly. There wil probably be an autumn meeting at which papers will be read and a field meeting next summer in some other part of Great Britain. It is proposed to publish a journal, which will be available to members under their subscription to the Society (21*s.* per annum), and to others at a subscription rate to be decided.

Education and Training of Aircraft Workers

THE Royal Aircraft Establishment of the Ministry of Aircraft Production has just issued an interesting and informative pamphlet on the general subject of aeronautical training. If, says the pamphlet, Great Britain is to maintain its superiority in the air, we must enlist the help of intelligent young men and young women, and give them a training in an attractive career full of possibilities. The basis of the scheme now proposed is the highly efficient technical college which has been built up as an integral part of the Establishment. The scheme set forth in the pamphlet is a system of apprenticeship, the apprentices being of three types: (1) engineering apprentices, who are trained to become aeronautical research engineers, and are drawn from boys who have attained a high standard of secondary school education; (2) craft apprentices, who are trained to become skilled craftsmen for service in laboratories and in experimental work; and (3) laboratory assistants, who are employed in the research laboratories, and must have obtained a school-leaving certificate with credit in science and mathematics. Details are given concerning the course of training for each of the three types of apprentice. The course in each case prolonged and thorough, and it is shown that for ch type there is the possibility and the promise of successful career.

/hat are Comets ?

Ciencia Investigación No. 2, February 1945, con-ins an article with the title "¿ Qué son los cometas ?" y Enrique Gaviola, director of the Córdoba Observa-ory, which gives a short account of comets from ncient times up to the present. There is nothing new the article, but it provides a useful summary of ur knowledge of these visitors, dealing with the ectrograms of the gases in the head and tail, the asses deduced by the perturbations or lack of per-urbations produced by comets, changes in luminosity ue to varying distances from the sun, light pressure n the smaller particles, etc. The author conjectures at the asteroids were once brilliant comets—a view hich is entertained by others, but lacking in con-usive evidence. There is a very fine photograph of Ialley's Comet taken at Córdoba Observatory on Iay 7, 1910.

ecent Earthquakes

DURING January 1945, ten earthquakes were egistered at the seismological observatory at Toledo, pain. The greatest of these was on January 12, hen an earthquake, registering initially at 18h. 52m. 1s. G.M.T., developed an amplitude of 50 μ at 19h. 6m. 13s. G.M.T. on the east-west component. The picentral distance has been provisionally estimated t 12,830 km. During the same month one strong istant earthquake was registered at the Dominion Observatory, Wellington, New Zealand. This was on January 28 at 07h. 37m. 18s. G.M.T. from an epicentral distance of approximately 22°. The shock was also registered at Christchurch, Auckland and Arapuni. In New Zealand there were twelve shocks humanly felt in the Dominion during the month. The greatest of these was on January 2. It was felt with intensity 5 (Modified Mercalli Scale) in the North Island, south of Wairo Taupo and Wanganui. On January 1 a shock was also felt at Wairo with intensity 5 (Mod. Mer.). The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the provisional epicentre of the earthquake of January 12 to be near lat. 34° N., long. 139° E., which is off the coast of Japan, to the south of Tokyo.

During February 1945, fourteen strong earthquakes were registered at the observatory at Toledo, Spain. The strongest of these occurred on February 10 and registered at Toledo at 05h. 11m. 09s. G.M.T., attaining a maximum ground amplitude at Toledo of 115 μ on the north-south component at 05h. 50m. 35s. G.M.T. The epicentral distance is estimated at 10,440 km. The shock of February 20 is estimated to have had its epicentre 660 km. from Toledo. The earthquake of February 18 was recorded at Kew, as was also that of February 26. The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the provisional epicentre of the earthquake of February 10, from instrumental reports from twenty-one observatories, to have been at lat. 41·5° N., long. 142° E., which is off the coast of Japan to the east of Hakodate. The initial time was 4h. 57·9m. G.M.T.

During March 1945, Mr. E. W. Pollard recorded seven earthquakes at his observatory at Binstead, Isle of Wight. Three occurred on March 18.

The Film in Science

THE Scientific Film Association is holding a conference on "The Film in Science" at the Technical College, Huddersfield, during August 31—September 2. The opening address will be given by Mr. Arthur Elton, president of the Association, and there will be sessions on the film in education, industry and medicine, and as an instrument of research. Dr. W. T. Astbury will give a lecture on the X-ray examination of proteins. There will be a display of visual aid equipment. Registration forms to attend the conference, and further particulars, can be obtained from the secretary of the Association, c/o Royal Photographic Society, 16 Princes Gate, London, S.W.7.

United Nations Educational Conference in London

A CONFERENCE is to be held in London on November 1 next to consider the establishment of a United Nations Educational and Cultural Organization. The Conference of Allied Ministers under the chairmanship of Mr. Richard Law, Minister of Education, at a meeting in London on July 12, unanimously agreed that the British Government be asked to invite on its behalf the Governments of all the United Nations to send delegates to this conference. A working committee will be set up in London to make preparations for the conference and to assemble and collate opinions and proposals as to the scope and methods of operation of the organization. Draft proposals for the constitution of the organization, prepared by the Conference of Allied Ministers, will be issued shortly and will form the basis of discussion at the forthcoming conference.

Announcements

DR. ALEXANDER S. WIENER, of New York University, has been awarded the Alvarenga Prize for 1945 of the College of Physicians of Philadelphia, "in recognition of his important work upon the various types of *Rh* factors and on their genetic transmission". Dr. Wiener will give the Alvarenga Lecture before the College of Physicians of Philadelphia and the Philadelphia County Medical Society on October 3, 1945, on "*Rh* Blood Factors in Clinical Medicine". This Prize was established by the will of Pedro Francisco daCosta Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, "to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883". The College usually makes this award for outstanding published work, and invites the recipient to deliver an Alvarenga Lecture before the College.

THE Council of the University of Sheffield has made the following appointments: Dr. H. Motz to be lecturer in engineering physics; Dr. James White to be lecturer in refractory materials in the Department of Metallurgy. Dr. C. Gray Imrie, lecturer in physiology, and Mr. J. MacA. Croll, lecturer in bacteriology, have resigned. Mr. C. H. Hainsworth, lecturer in electrical engineering, and Dr. W. J. Rees, lecturer in refractories, are retiring under the age limit. The Yorkshire Mine Workers' Association is to provide two scholarships in 1946, each of an annual value of £180, open to members of the Association and tenable for a full-time degree course in mining at the University.

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Anærobic Metabolism of Spermatozoa

It was shown by Iwanow[1] and Redenz[2] that the presence of oxygen is not essential for the survival of the spermatozoa and that they retain their motility under anærobic conditions provided that glucose is present. Later, it was demonstrated conclusively that the metabolism of spermatozoa is predominantly of glycolytic character[3,4,5,6,7]. Up to the present, however, the studies have been largely confined to the investigations of optimal conditions, various substrates and inhibitors of sperm glycolysis, leaving open the question concerning the glycolytic pathways and the enzymes involved in the anærobic processes. The presence in sperm of adenosinetriphosphate, one of the essential factors of glycolysis, has been assumed on the grounds that the sperm contains a phosphate fraction which breaks down to *ortho*-phosphate after short hydrolysis in acid[8].

The experiments recorded below were carried out mainly with ram semen, which is particularly suitable for metabolic studies because of the exceptionally high concentration of spermatozoa (2·5–5 million per 1 µl. semen). The semen was collected by Dr. A. Walton and Dr. L. Villalobos at the Animal Research Station, Cambridge. It was brought to the laboratory within an hour after ejaculation, it was then diluted with 5–10 volumes of calcium-free Ringer-bicarbonate solution, centrifuged, and finally the sperm was re-suspended in fresh Ringer solution up to the original volume of the whole semen. Aerobically, such a suspension has a high respiratory activity which remains constant for several hours and compares favourably with the respiration of the whole semen. In the presence of added glucose, the respiration is partly replaced by an ærobic glycolysis. Spectroscopic examination of the sperm suspension reveals the spectrum of all three cytochromes. When air is replaced by nitrogen or by a mixture of 95 per cent nitrogen and 5 per cent carbon dioxide, the cytochromes become fully reduced and the glycolysis rises to reach a level of 100–600 mgm. lactic acid per 100 ml. sperm, per hour, at 37°. With such a sperm suspension the following observations were made.

(1) Spermatozoa contain adenosinetriphosphate which was isolated quantitatively in the form of the barium salt. The amino-group was identified by means of the muscle deaminase, the phosphate groups by acid hydrolysis and subsequent estimation of *ortho*-phosphate. The content was 0·6–1·5 mgm. per cent amino-nitrogen and 2·6–6·6 mgm. per cent easily hydrolysable phosphorus.

(2) When spermatozoa are incubated anærobically without glucose, their content of adenosinetriphosphate decreases rapidly, while in the presence of glucose it can be preserved much longer. This behaviour is in agreement with the observation that in spermatozoa stored anærobically motility is maintained more satisfactorily in the presence than in the absence of a glycolysable substrate.

(3) The metabolism of glucose in the sperm is initiated by the shift of the labile phosphate groups from adenosinetriphosphate to glucose. The enzyme which catalyses this reaction resembles the hexokinase of yeast. Using 1 ml. of sperm to which gluco adenosinetriphosphate and 0·04 N fluoride w added, one finds after one hour at 37° that nea half the readily hydrolysable phosphorus of adenosi triphosphate is esterified with the hexose. Witho fluoride a large proportion of adenosinetriphosph breaks down rapidly with the liberation of all th phosphate groups as *ortho*-phosphate. This brea down, however, unlike that in certain other anim tissues, is not accompanied by the deamination the amino-group of the nucleotide; in fact, it h been found that the semen has scarcely any deami ase activity towards adenosinetriphosphate, adeny acid and adenosine. But in semen kept for seve hours under sterile conditions, large amounts ammonia accumulate. This evolution of ammon does not depend on the presence of intact sperm tozoa; it occurs also in the seminal fluid itse Furthermore, it is accompanied by a sharp rise the non-protein nitrogen, which exceeds considerab the ammonia nitrogen.

(4) Monophosphohexose added to a suspension surviving sperm is further phosphorylated in t presence of adenosinetriphosphate. To study t action of the phosphopherase involved in this r action, the Embden ester was used. This compou was scarcely metabolized by the sperm alone an yielded no lactic acid. However, on the additio of adenosinetriphosphate, the Embden ester wa phosphorylated to diphosphohexose and lactic aci was produced. Of 2 mgm. phosphorus added a monophosphohexose to 1 ml. sperm, 26 per cen appeared after 30 min. as readily hydrolysable phosphorus of diphosphohexose.

(5) Diphosphohexose is broken down by spermatozoa and oxidized to phosphoglyceric acid. Th oxidation is coupled with a reduction of pyruvi acid to lactic acid. This reaction is inhibited by 0·001 N iodoacetate but not by 0·04 N fluoride. Th dehydrogenases which catalyse the oxido-reductio depend for their activity on the presence of cozymase. The oxido-reduction is coupled with a phosphorylation of adenylic acid to adenosinetriphosphate. One molecule of lactic acid is formed for each molecule of inorganic phosphate which disappears. For example, 1 ml. sperm incubated anærobically at 37° for 30 min., with 0·6 ml. 0·3 N pyruvate, 0·3 ml. 0·15 N diphosphohexose (Harden – Young ester), 0·4 ml. 0·16 N adenylate, and in presence of cozymase, inorganic phosphate pH 7·3 and 0·04 N fluoride, brought about the disappearance of 1·37 mgm. inorganic phosphorus, and the formation of 3·77 mgm. lactic acid; and synthesized an amount of adenosinetriphosphate corresponding to 0·318 mgm. amino-nitrogen and 1·4 mgm. readily hydrolysable phosphorus.

(6) Phosphoglyceric acid added to the sperm is metabolized very slowly. However, in the presence of adenylate it is rapidly converted to pyruvic, and eventually to lactic acid. The phosphate group of phosphoglyceric acid is taken up by adenylic acid, and reconstituted adenosinetriphosphate is made available again for the initial stages of glycolysis, namely, the phosphorylation of hexose and of monophosphohexose. When 1 ml. sperm was incubated anærobically for 30 min. with 3 mgm. phosphorus in the form of phosphoglycerate, the result was 0·13 mgm. pyruvic acid, 0·3 mgm. lactic acid and 0·25 mgm. inorganic phosphorus. In presence of adenylate, however, the same amount of phosphoglycerate yielded 3·45 mgm. pyruvic acid, 1·62 mgm.

tic acid, 1·3 mgm. inorganic phosphorus, 30 per t of the added adenylate being converted to mosinetriphosphate.

7) All these enzymic processes are not necessarily tricted to anærobic conditions but occur in obically glycolysing spermatozoa as well. They o take place in the sperm of other animals. Bull nen, for example, contains 0·4 mgm. per cent of enosinetriphosphate amino-nitrogen and is distinguished by a high rate of the phosphorylative ido-reduction. No lactic acid is produced from cogen by washed spermatozoa of either ram or bull.

Two major points emerge from this investigation. e fact is established that a close relationship exists tween the activity of the spermatozoa on one hand, d the glycolysis mediated by adenosinetriphosate on the other hand. Next, it is shown that the ycolytic pathways and enzymes involved in the ærobic metabolism of spermatozoa bear resemblance those of other animal tissues and yeast. Hitherto, e study of enzymes concerned with the glycolysis volved for the most part the use of purified systems parated from the cell structure (for example, uscle, yeast); objections were occasionally raised at results obtained in this manner may not depict e true function of those enzymes inside the cells. owever, with spermatozoa the course of reactions talysed by the glycolytic enzymes has been exored in the cells themselves.

This work is being carried out on behalf of the gricultural Research Council.

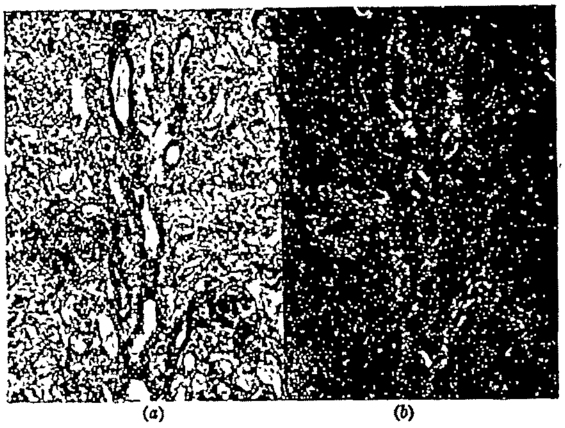
Double-Refringence of the Amyloid-Congo-Red-Complex in Histological Sections

The Congo-red reaction of amyloid in histological ections is the only amyloid stain providing durable preparations. It has, however, so far proved of imited value, as its specificity is compromised by certain hyaline, mucous, fibrinoid or elastic tissue components also 'taking' Congo-red.

We have been able to show that this method can be brought to a very high level of specificity by using it in combination with polarization microscopy. Amyloid structures unstained or stained by the usual routine and other specific methods present no double-refringence of practical importance; but they reveal a very sharp, though not particularly sparkling, optical anisotropy after Congo-red staining (see reproduction). For demonstration, a very bright, unfiltered light source was used. The colour of the effect changes during rotation through 360° of the optical axes of the preparation twice from yellow to green, if conditions are optimal. Other Congo-positive but non-amyloid tissue components do not show this newly acquired double-refringence. Certain hyalines, etc., however, may be strongly anisotropic by themselves, a fact which is argument enough against their being regarded as amyloid.



Kidney (No. Pl. 98/45). Cortical zone with amyloid degeneration of interlobular artery and two Malpighian bodies. Formalin-fixing, paraffin section, 7 μ, hæmatoxylin Congo-red stain: (*a*) between parallel nicols; (*b*) between crossed nicols. × *c*. 50.

Besides the practical importance in histopathology of the phenomenon reported, this 'induced double-refringence' may well be of theoretical interest in connexion with the submicroscopical make-up of amyloid and the physico-chemical mode of interaction between Congo-red as a specific staining matter and amyloid as its 'substratum'. It would, indeed, be most interesting to study similar cases of more or less isotropic systems becoming doubly-refringent by their interaction with isotropic colloidal solutions.

The following details on the effect have so far been gathered (in all experiments, Congo-red from E. Merck, Darmstadt, was used): (1) Congo-red precipitates show no direct optical anisotropy, and Congo-red solutions show no stream double-refringence. (2) The effect depends on the actual presence of Congo-red in the amyloid structures; if the stain is washed out from a section, the double-refringence formerly established disappears. Moreover, the double-refringence appears brighter the more strongly the stain has 'taken', a ratio in which the thickness of the section is equally involved. (3) The effect can be observed in slices mounted in balsam as well as in glycerol, glycerol-gelatine or physiological salt solution. Freezing and paraffin sections do not make any appreciable differences in producing the effect. (4) As to the effect of tissue-fixing, the 'pictures' resulting from formalin and alcohol fixation are equally good. Material fixed in Zenker's solution (containing mercuric chloride, potassium bichromate and acetic acid) proved, however, less favourable; apart from the fact that precipitates occurring in the sections are disturbing by their sparkling double-refringence, the effect, in itself, seems to be far less obvious, even if the precipitates are totally or partly removed by iodine treatment, notwithstanding the fact that the amyloid structures are showing a brilliant Congo-red stain. This might well be the effect of blocking certain reactive groups in the amyloid molecule complex by chromium or mercury, groups which otherwise would have taken part in the reaction with Congo-red. Experiments on this are still in progress; it may be mentioned, however, that iodine treatment of alcohol-fixed material, previous to Congo-red staining, does not necessarily cause a reduction of the ensuing double-refringence. (5) Among acid diazo-stains chemically related to Congo-red and so far tested for similar properties, only Congo-rubin has been found to produce a certain induced anisotropy with amyloid; this effect, however, is not so readily reproduced as in the case of Congo-red. Trypan-red and trypan-blue may or may not have a very slight similar effect.

The following preliminary conclusions have been drawn from the observations: the double-refringence produced by the interaction of amyloid and Congo-red is an essential and not an accidental one; this is evident by its being largely independent of the refractive index of the imbibition liquid. The amyloid-protein substructure seems to include reactive groups in a certain regular distribution and arrangement in space which allow the Congo-red molecule complexes to fit in by means of corresponding reactive groups in such a way as to create a crystal-like structure.

Stabilization of Penicillin Solutions by Phosphate

ALTHOUGH penicillin in aqueous solution is rather more stable than was originally supposed, there is, nevertheless, an appreciable loss of activity in a few days at room temperature and in a few minutes at 100° C. We have found it possible greatly to stabilize penicillin solutions by the addition of phosphate (Sørensen's buffer solution). That this is not due to an effect on *p*H was shown by parallel experiments with penicillin in water alone, the *p*H of which was carefully regulated to that of the phosphate solutions.

The degree of stabilization depends on the sample of penicillin, the concentration of penicillin in the solution, and the concentration of phosphate. For example, in 15 min. at 100° C. and a concentration of penicillin of 5 u./ml., one sample lost 50 per cent of its activity in water and 5 per cent in *M*/15 phosphate; a second sample lost 25 per cent in water and 5 per cent in phosphate (see table). Different samples differ also in the amount of phosphate which gives maximal protection; with a concentration of 5 u./ml. penicillin, one sample was protected most by *M*/100 phosphate; a second by *M*/30 phosphate, whereas with a third there was increasing protection with increasing phosphate concentration up to and apparently beyond *M*/3 phosphate.

DESTRUCTION OF PENICILLIN SOLUTIONS AT 100° FOR 15 MIN. IN THE ABSENCE AND PRESENCE OF PHOSPHATES. FIGURES GIVE PERCENTAGE PENICILLIN DESTROYED. PHOSPHATE CONCENTRATION *M*/15.

Sample	Concentration of penicillin							
	5 u./ml.		50 u./ml.		500 u./ml		5,000 u./ml.	
	water	phosphate	water	phosphate	water	phosphate	water	phosphate
1	50	5	10	15	30	10	35	5
2	50	5	50	10	70	20	50	15
3	25	5	—	—	5	10	30	10

There are several practical applications of these findings. Perhaps the most important is that solutions of penicillin, which frequently become contaminated with organisms such as *Ps. pyocya* may be sterilized by boiling for a few minutes in presence of phosphate, with but little loss in poten Secondly, if only small quantities of penicillin required out of the usual phial of 100,000 units, addition of phosphate will make it possible to k the unused portion of the solution for several d with little loss of activity.

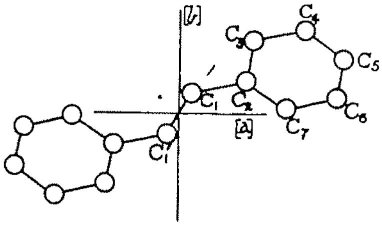
Structure of Dibenzyl

WITH the early work of J. M. Robertson[1] a sound basis, the crystal structure of dibenzyl been determined more accurately, using more th seven hundred experimental structure amplitudes modern three-dimensional Fourier methods, includi the new syntheses devised by A. D. Booth[2]. For t first time in Great Britain, professional aid w enlisted for the laborious calculation of the fi Fourier synthesis and theoretical structure fact through the co-operation of the Scientific Computi Service.



C_6H_5-CH_2CH_2-C_6H_5

The molecule of dibenzyl has a centre of symmetr and with the nomenclature shown in the figure th interatomic dimensions are as follows:

$C'_1—C_1$	1·48 A.	$C_4—C_5$	1·36$_5$ A.
$C_1—C_2$	1·50	$C_5—C_6$	1·36$_5$
$C_2—C_3$	1·37	$C_3—C_4$	1·39
$C_2—C_7$	1·36	$C_6—C_7$	1·39

$C'_1C_1C_2 = 115°$; all angles associated with the benzen rings, 120 ± 1°. The C'_1C_1 bond is inclined at 72° t the plane of the benzene rings.

The atomic parameters were derived directly fro the maxima of the Fourier peaks, and no assumption were made about the fine details of the structure It is therefore possible to get a measure of th accuracy of the analysis from the geometry of th molecule; for example, the opposite sides of th benzene ring are parallel and $C_1—C_2$ is collinear wit $C_2—C_5$ within 0·5°. Discrepancies of this orde suggest that the values given above are reliable t ±0·01 A. and ±1°.

The special interest of these results lies in th acyclic single-bond distances, which are shorter than the normal value of 1·54 A. The system of two benzene rings separated by three single bonds is analogou to the 1:5-dienes and polyisoprenes, and that it should possess unusual structural features is in keeping with observations on this class of compounds instanced by the chemistry of certain carbalkoxyl derivatives of hexadiene[3] and the structure of geranylamine hydrochloride[4].

detailed description of the structure analysis discussion of the results will be published else- ere.

Crystal Structure of Diamond

N a recent communication in *Nature*[1], Mrs. Lonsdale s questioned the statement made by Sir C. V. Raman[2] t the X-ray data leave the question whether mond possesses tetrahedral or octahedral sym- try of structure entirely open. The present com- nication is a reply to some of the specific points sed in her letter.

As is well known, the structure of diamond consists two interpenetrating face-centred cubic lattices, two atoms in the basis having the co-ordinates 0 and $\frac{1}{4}\frac{1}{4}\frac{1}{4}$. From the fact that the atoms occupy ese special positions in the lattice, it follows that ey must possess tetrahedral (*Td*) symmetry of ucture, which may be visualized by drawing a set planes passing through the atomic nucleus and rallel to the cubic and dodecahedral planes, and ereby dividing up the whole electronic cloud into 4 pyramids. Tetrahedral symmetry requires that the charge distribution in one of these pyramids specified, those in 23 others should also be the same, ese 24. pyramids being distributed (six each) in ur non-adjacent octants of the sphere drawn round e nucleus. The charge distributions in the remain- g 24 pyramids would also be identical, but different om those in the first set.

As a consequence of the tetrahedral symmetry the atoms, the crystal as a whole would also ossess the same symmetry, except in the special ase when the electronic states and configurations of e two atoms are exactly identical and geometrically ymmetric about a point midway between them $\frac{1}{8}, \frac{1}{8}, \frac{1}{8}$). It is easily proved, however, that this special elationship, which results in a higher or octahedral ymmetry for the crystal, is not a necessary condition ither for the non-appearance of the 200 X-ray re- exion nor for the appearance with a low intensity f the 222 X-ray reflexion. The vanishing of the 00 reflexion is secured if the radial distribution of lectronic charge, when *summed up* for a pair of pposed pyramids in each atom, is the same for oth the atoms in the basis. This means that the otal charge in a spherical shell surrounding the ucleus, and consequently also the integrated total harge, is the same for both atoms. The fact that iamond does not exhibit either piezo- or pyro- lectricity thereby becomes intelligible. Further, the 222 X-ray reflexion would only vanish in two special ases, namely, (*a*) when each atom is octahedrally symmetrical, or (*b*) when the atoms are tetrahedrally symmetrical, but the radial distributions of charge are identical in similarly directed pyramids in the two atoms.

Prima facie, neither of these special conditions can be expected to exist; as a result of the valence binding, the electronic distribution would in general tend more towards identity in opposing pyramids than in parallel ones. The appearance of a 222 reflexion is thus naturally to be expected. But any departure, however small, from identity and symmetry of the distributions in opposing pyramids would result in the structure as a whole possessing only tetrahedral and not octahedral symmetry. The spectroscopic behaviour of diamond shows beyond all possibility of doubt that this is so in the majority of cases.

Energy Spectrum of Mesotrons at Low Energies

THE energy spectrum of cosmic rays has been studied by means of magnetic analysis by Blackett[1], Jones[2] and Hughes[3]. In the present experiment, information regarding the low-energy part of the mesotron spectrum has been obtained from analysis of the absorption curves of cosmic rays in lead and water.

The curves *ABCDE* and *AIJK* in Fig. 1 represent the absorption curves of cosmic rays in lead and water respectively taken under identical conditions. In each case the variation in the number of coincidences with different thickness of absorber interposed between the upper counters of a counter telescope is represented as a function of the absorber thickness.

In the analysis of these curves, it is assumed that the part *CDE* of the lead absorption curve, obtained with a thickness of lead greater than 10 cm., is entirely due to cosmic ray mesotrons. The portion *ABC*, corresponding to a thickness of lead less than 10 cm., represents the rate of absorption of electrons of all energies and of mesotrons with range less than 10 cm. lead or pc less than $2 \cdot 3 \times 10^8$ e.v. (Rossi and Greisen[4]).

The effect of the electronic part of the cosmic radiation transmitted through different thickness of an absorber may be determined from a comparison of the relative absorption in two substances (Greisen[5]). Then by subtraction from the total absorption curve, the rate of absorption of mesotrons alone, separated from that of the electrons, may be obtained.

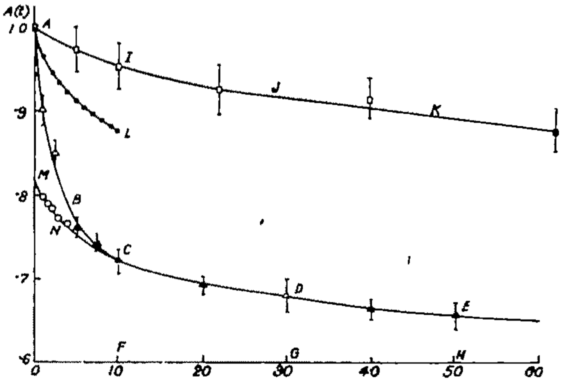

Fig. 1.

We choose water and lead as the two absorbers because the critical energies of these substances differ very greatly. In the case of water, the critical energy is higher and is $1 \cdot 1 \times 10^8$ e.v. As the radiation loss for electrons becomes appreciable for energies higher than the critical energies, and as at sea-level there are very few electrons above 10^8 e.v., one may reasonably assume that the water absorption curve *AIJK* represents mainly the rate of stoppage of electrons and mesotrons due to ionization only.

Now, so far as ionization loss is concerned, 1 cm. of water is equivalent to 0·16 cm. of lead. With this reduction ratio, the curve *AIJK* may be reduced to the lead scale. The reduced curve is shown by *AL*. *AL* represents the rate of absorption of cosmic particles in lead if there were no radiation loss, whereas the actual curve *ABC* represents the rate of absorption of mesotrons due to ionization and of electrons due both to radiation and ionization.

If we extrapolate the absorption curve beyond 10 cm. which is due to mesotrons only in the same ratio as the curve *AL*, we obtain the complete absorption curve of mesotrons and of those electrons which are stopped due to ionization in lead, that is, with energies below the critical energy of lead, 7×10^6 e.v. The curve *MNCDE* obtained in this way really represents the absorption of cosmic ray mesotrons in lead, as electrons with energies less than 7×10^6 e.v. will be stopped by the walls of the counter.

As a check on this result, we have used the calculations of Bhabha[6]. He recently estimated the number of cosmic ray electrons that may be expected to be recorded at sea-level by means of a counter telescope, such as we have used, with different thicknesses of lead interposed between the counters. The ordinates of the total lead absorption curve *ABC* may be corrected for the number of transmitted electrons as suggested by Bhabha. The calculated points indicating mesotron intensity alone are shown in the graph by circles and are found to lie on the curve *MNCDE*, proving that this is entirely due to cosmic ray mesotrons.

In order to obtain the differential energy spectrum from the absorption curve, we assume that for a mesotron of a definite energy E, there is a fixed range of R cm. of lead. The ordinate of the absorption curve $A(t)$ at a thickness t cm. may then be represented as

$$A(t) = \int_t^{R_0} n(R)dR = \int_E^{E_0} n(E)dE, \quad . \quad . \quad (1)$$

where $n(R)dR$ and $n(E)dE$ represent the fractional number of mesotrons with range between R and $R + dR$, or with energy between E and $E + dE$. The limits of the integrals extend from any thickness t of the absorption curve or from the corresponding energy E of the energy distribution curve to the maximum range R_0 or the limiting energy E_0 of the mesotron spectrum. Then

$$n(E) = -\frac{dA}{dE} = -\frac{dA}{dt} \Big/ \frac{dE}{dt} \quad . \quad . \quad (2)$$

$\frac{dA}{dt}$ is determined from the corrected absorption curve *MNCDE* and $\frac{dE}{dt}$ for mesotrons of mass 200 m. has been calculated by Rossi and Greisen[4]. Thus the differential mesotron spectrum may be obtained from the absorption curve.

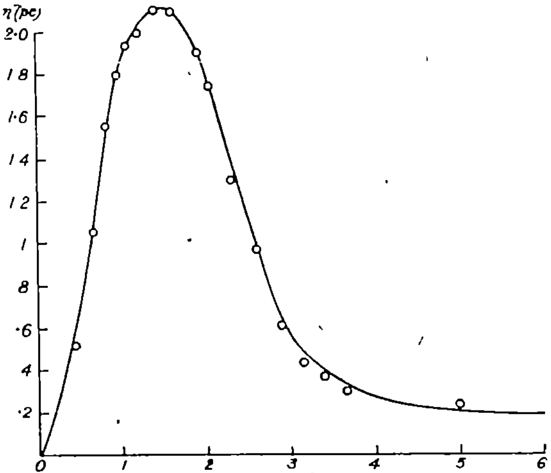

Fig. 2. Differential mesotron spectrum.

The result of the above analysis is shown in Fig. The shape of the differential spectrum is similar that obtained by Jones and Hughes, but the peak the spectrum appears to be shifted to much low energies. The results therefore show that there i considerably larger number of slow mesotrons sea-level than is commonly believed; these sl mesotrons are possibly excluded in counter-controll cloud chamber measurements. Alternatively, it also possible that dE/dt for low-energy mesotrons much greater than that given by the simple ionizati formula.

Our thanks are due to Prof. M. N. Saha for pr viding facilities for this work and for his continu interest in it.

Production of Difference Tones

IN providing a course of instruction in preliminar radio physics for war purposes, there were in ou laboratory several audio-frequency generators whic were capable of producing tonal frequencies up t and above the limits of hearing. It occurred to m that with two such instruments difference tones migh easily be generated. The instruments were connected, preferably in parallel, with a small loud speaker, and the pitch of each was gradually raised by itself to a frequency just above the limit of audibility When both instruments were simultaneously adjustec by the dial to the same high frequency, no tone wa heard. But when one of them was altered to a smal extent, a deep low difference tone of a frequency near the lower limit of audibility was loudly heard by itself. By gradually changing the frequency of on generator, the pitch of the difference tone rises con uously to any height desired. It is sufficiently loud be heard over a large lecture room, and is now so monstrated.

It makes a very convincing experiment to produce difference tone when all three tones are heard once, and then gradually raise the pitch of the nerating tones above the audibility limit, finally ving the difference tone to be heard alone. The ect is by far the best that I have ever been able obtain with 'tonvariators' of any kind. The method ems to be of no use in generating audible summation nes since, as in all methods, the necessary low tones ask the summational higher ones. It may be the se that this method of generating difference tones s been used by others though I have never seen reference to it.

Prof. H. F. Batho has directed my attention to e fact that difference tones can also be produced two radio-frequency generators similarly arranged, here the generating frequencies are of the order of couple of thousand kilocycles per second. In this se the variable condenser which changes the freency of one generator needs to have its capacity tered only a very small amount in order to cover e audible range. But more gradual tuning can be ade by connecting a second small variable conenser in parallel with the first, so that a considerable ovement of the plates of the second will be required carry the pitch of the difference tone through the nge of audibility. It is interesting to note that ifference tones can be generated by two frequencies f any magnitude up to several million cycles per econd.

Units for Degree of Vacuum

MR. TOWNSEND's recent suggestion for a new unit for degree of vacuum based on the logarithm of the numerical value of the pressure in millimetres of mercury is to be welcomed. The new unit successfully removes the clumsy expressions of the present convention. It is also appropriate to adopt 1 mm. mercury pressure as the reference-level for the new system with logarithm of a pressure ratio.

In defining the new unit there is, however, no need to have an analogy with the definition of the decibel in the method of measuring power ratios; the analogy should rather be with the definition of the bel, one decibel being one tenth of a bel, and being used for the sake of obtaining more convenient quantities in communication engineering problems. Thus the new pressure unit ('vacuum unit') should be defined so that a pressure of a mm. of mercury becomes $A = \log_{10} \dfrac{1}{a} = -\log_{10} a$ 'vacuum units'.

May I further be allowed to suggest that the name for the new unit might be "McLeod". A pressure of, say, 1×10^{-5} mm. Hg would thus read 5 McLeods, 1×10^{-6} mm. Hg would become 6 McLeods, and 3×10^{-6} mm. Hg would be equal to $6 - \log_{10} 3 = 5{\cdot}52$ McLeods.

Manchester.

---

[1] *Nature*, **155**, 545 (1945).

I SHOULD like to comment on Mr. F. H. Townsend's[1] recent communication to this journal, in which he proposed a logarithmic scale of pressure for high-vacuum work.

These new vacuum units provide us with a valuable method for measuring pump speeds. When a pump evacuating a closed vessel into which leakage is inappreciable—a case of great practical interest—is operating at constant speed by volume, the pressure in the vessel is falling exponentially towards zero. Thus the height of vacuum measured in Townsend's units is increasing linearly. I suggest, then, that the speed of a pump may be measured by the rate of increase of vacuum (in the new units) which it produces in such a closed volume of standard size. In fact, if the speed of the pump be V volume units per second, it is 10 V vacuum units per volume unit per second, taking the volume of the standard vessel equal to the original unit. Thus the maximum speed of the pump referred to in Mr. Townsend's letter is 860 'vac.'/cu.m./hr. at 38 'vacs.'. An advantage of this method is that the calculation of how long it will take to exhaust a given vessel to a given vacuum affords rather less scope for arithmetical errors.

As regards naming the new unit, why not call it 'vacuum unit' and, as above, abbreviate it to 'vac.'?

Hexachlorocyclohexane as an Insecticide

MR. E. L. TAYLOR has given[1] an account of work on the acaricidal properties of a 'new' insecticide of the general formula $C_6H_6Cl_6$ (hexachloro*cyclo*hexane). This substance has been available in France for some years under the trade name of 'Aphtiria'. It would appear that a patent covering the method of preparation was taken out in France by M. Louis Gindraux in 1941. It has been used as an insecticide during the War in large quantities by the French Government with excellent results.

The disagreeable odour which is associated with hexachlorobenzene can be masked fairly easily, as the concentration of the active agent is rarely above 2 per cent when used as an insecticide. M. Gindraux (in a personal communication) believes that it is possible to prepare it free from an offensive smell and is engaged actively on the problem.

As most of the experiments which have been conducted have necessitated the use of organic solvents such as acetone, kerosene, etc., it should be noted that these are themselves active causers of dermatitis in man and that cases of skin involvement are common when used in industry.

It is, however, possible that a satisfactory cream will be produced containing an adequate concentration of hexachloro*cyclo*hexane which can be used for the treatment of scabies in man.

THE VITAMIN B_2 COMPLEX

AT a joint meeting of the Nutrition Society and the Biochemical Society held on April 28, at the London School of Hygiene and Tropical Medicine, the subject of the vitamin B_2 complex was discussed. The chairman of the morning session, Prof. R. A. Peters, reviewed the early history of vitamin B, describing the experiments on the basis of which the heat-labile vitamin B_1 was differentiated from the heat-stable vitamin B_2, and the composite nature of the heat-stable component was eventually recognized. He read a prophetic passage from a letter written many years ago by Sir Charles Martin, suggesting that vitamin B might be composed of several different factors.

The story was further elaborated by Dr. L. J. Harris and Dr. E. Kodicek in a paper entitled "The Nutritional Significance of the Vitamin B Complex". The vitamin B_2 complex can be sub-divided into the adsorbable factors nicotinamide, riboflavin and pyridoxine, the filtrate factors pantothenic acid, *p*-amino benzoic acid, inositol and choline, and a third group comprising biotin, the folic acid group and the grass juice factor. The history of each of these factors and their biological properties were discussed in turn.

Nicotinamide cures pellagra in man, black-tongue in dogs and a corresponding condition in monkeys and pigs. Riboflavin deficiency in man is accompanied by characteristic symptoms. Deficiencies of pyridoxine and pantothenic acid cause a dermatitis in rats and chickens respectively, while biotin cures a seborrhœic pellagra in rats caused by the avidin of egg-white. Choline is a biological methylating agent and can be replaced by methionine. The relationship between folic acid, vitamin B_C, vitamin H and the *L. casei* ε factor was briefly discussed. Nicotinic acid, riboflavin and probably pyridoxine, like aneurine, are components of enzyme systems essential in carbohydrate metabolism.

This point was discussed in more detail by Dr. J. H. Quastel, in a paper on "The Parts Played by Members of the Vitamin B Complex in Enzyme Systems". Aneurine pyrophosphate is co-carboxylase, the coenzyme of pyruvate oxidation; as such, it catalyses a large number of reactions. Magnesium takes an important role in the transformation of pyruvic acid, and may be part of the enzyme carboxylase. Aneurine also appears to be necessary for the oxidation of α-keto-glutarate, important in transaminations and in the oxidation of acetic acid. Nicotinic acid is present in the coenzyme involved in hexose monophosphate oxidation and in cozymase, the coenzyme of alcoholic fermentation. During oxidation of the substrate it undergoes reduction, and is afterwards reoxidized by flavo-protein, the nicotinamide nitrogen being the site of the successive oxidation and reduction. Cozymase combines with numerous specific proteins to form dehydrogenases capable of oxidizing a variety of substrates. It is also associated with amino-acid oxidations, since in transaminations it catalyses the reconversion of glutamic acid into α-ketoglutaric acid. Riboflavin is also a component of a respiratory enzyme, flavo-protein, which will oxidize reduced cozymase; the *iso*alloxazine nucleus is the seat of the oxido-reductive changes. Reduced flavo-protein is auto-oxidizable, but *in vivo*, it is oxidized by cytochrome; it can also be oxidized by such dyestuffs as methylene blue and by pyocyanine. Pyridoxine is also part of an enzyme system, pyridoxal phosphate being identical w tyrosine decarboxylase, while pantothenic acid believed to be concerned with pyruvate metabolis

Mr. F. A. Robinson discussed "Some Recen Characterized Members of the Vitamin B_2 Comple He distinguished between aneurine, riboflavin a nicotinic acid, which are associated with clea defined deficiency diseases, and the other members the vitamin B_2 complex, which are not. Pyridoxi was the first of the newer factors to be characteriz and synthesized, and recently two of its derivativ pyridoxal and pyridoxamine, have been shown to concerned with transaminations, while pyrido phosphate is apparently identical with tyrosi decarboxylase. The 'filtrate factor', now call pantothenic acid, and biotin have also been sy thesized. All three of these substances are componen of 'bios' and are essential for the growth of a numb of micro-organisms. Uncomplicated biotin and pant thenic acid deficiencies, not artificially induced, ha not been encountered in man. Another substan which was first recognized by its ability to stimula the growth of micro-organisms is folic acid. Th appears to be identical with a growth-factor f chicks, the so-called vitamin B_C, and with th so-called *L. casei* ε factor; both vitamin B_C and fol acid prevent anæmia and leucopenia in chick Recently it was shown that α- and β-pyracin, th lactones of the acids derived from pyridoxine, als prevent anæmia in chicks. Folic acid also preven the anæmia and other symptoms induced by ad ministration of certain sulphonamides, and part relieves the symptoms of vitamin M-deficiency i monkeys. These are also partially relieved b xanthopterin, the fish anæmia factor, while folic aci is partially effective in fish anæmia. There appear to be a close chemical as well as biological relation ship between these factors, but this cannot be substantiated until pure folic acid is available. *p*-Amino benzoic acid is another growth-factor for micro organisms now included in the vitamin B_2 complex and a large number of others have recently bee described about which little is as yet known. Th lipotropic factors, inositol, choline and methionine which prevent fatty-liver formation, are regarded as constituting a third sub-group of the vitamin B_2 complex.

Dr. B. C. J. G. Knight read a paper on "Growth-Factors and Growth Inhibitors for Micro-organisms". He gave a list of the growth-factors known to be required by different micro-organisms; some of these are themselves components and possibly precursors of more complex factors. Researches into growth-factors indicated that certain fundamental metabolic processes are common to the life of all cells, and Fildes suggested the term 'essential metabolite' to indicate a substance which participates in such processes. An essential metabolite that cannot be synthesized by an organism is a growth-factor for that organism. Woods showed *p*-aminobenzoic acid to be a specific antagonist for sulphanilamide, and predicted that *p*-aminobenzoic acid would be an essential metabolite. The prediction has been fulfilled and has led to a search for other growth-inhibitors capable of antagonizing known growth-factors. As a result, inhibitors such as pyridine-3-sulphonic acid and 3-acetylpyridine modelled on nicotinic acid, pantoyl taurine and *iso*riboflavin modelled on pantothenic acid and riboflavin respectively, and others modelled on biotin had been prepared. It has also been discovered that the antibiotic effects of mepacrine, thylene blue, quinine and propamidine are neu- lized by riboflavin, but the antagonistic action is bably more complex than in the other instances en. The growth-stimulating properties of aneurine neutralized by pyrithiamine, the effect being nplete or partial according to whether the organ- as require the whole or only a part of the aneurine lecule. It had also been observed that the pyro- osphate of the thiazole moiety of aneurine will ibit carboxylase activity, suggesting that cocarb- ylase and the thiazole pyrophosphate compete th one another for the carboxylase protein.

Dr. F. Bergel, opening the discussion on these pers, said there are reasons for differentiating tween the major vitamins, aneurine, riboflavin and otinic acid, and the minor vitamins, other than reasons mentioned by Mr. Robinson. He pointed t that the major vitamins are highly specific in eir action, only very closely related substances ing effective, whereas the minor vitamins can be placed by a number of analogues, and he cited ntothenic acid and its derivatives as an example. her speakers in the discussion, however, deprecated e attempt to distinguish between major and minor tamins, and suggested that in a few years time, th groups may be regarded as equally important. ere was also disagreement with the suggestion that ic acid, vitamin Bc and the *L. casei* ε factor are entical.

At the afternoon session, under the chairmanship Dr. L. J. Harris, Dr. B. S. Platt read a paper on ermentation and Human Nutrition". He showed series of slides, illustrating the manufacture of affir beer, and compared its nutritional value with at of British beer. Although the latter contains preciable quantities of vitamins, it contains far less an Kaffir beer, and it was believed that this drink pplies factors which are otherwise lacking in the ative diet. This was clearly brought out by a study f natives in the West Indies, who suffered from arious deficiencies such as greying of the hair, heilosis and various forms of dermatitis unknown mong similar races in Africa where Kaffir beer is a taple article of diet. Investigation showed that when ereal grains germinate, the amounts of most members f the vitamin B complex present increase and that nost of these factors are extracted in the steeping rocess, so passing into the resulting liquor. Although uminants undoubtedly rely on fermentation in the umen as the main source of supply of the vitamin B actors, it is not yet possible to state with certainty what contribution is made by bacterial fermentation n the intestinal tract to the vitamin requirements of an. Later, Dr. Platt showed a series of slides, some n colour, illustrating the symptoms of vitamin eficiency encountered during his recent visit to Labrador and Newfoundland.

Dr. Lucy Wills spoke on "The Vitamin B Complex in Anæmia", dealing especially with nutritional macrocytic anæmia and its relation to Addisonian pernicious anæmia. Nutritional macrocytic anæmia has formerly been regarded as due to a deficiency of an extrinsic factor which, according to Castle, is converted by the action of the intrinsic factor in the gastric juice into the anti-pernicious anæmia factor, which is stored in the liver. If Castle's theory is justified, nutritional macrocytic anæmia should be cured by any extract active in pernicious anæmia however given, but this is not the case. Dr. Wills therefore advanced an alternative theory, that this type of anæmia is due to the absence of a factor belonging to the vitamin B_2 complex which does not, as Castle postulated, react with the intrinsic factor to give the liver principle, nor is it an essential part of the latter, though necessary for its proper functioning. In support of this theory, Dr. Wills stated that uncomplicated nutritional macrocytic anæmia in Bombay does not respond to purified liver extracts, but does respond to crude liver extracts and to yeast extracts by injection as well as by mouth. Furthermore, monkeys, in which a similar type of anæmia has been artificially induced, also respond to crude, though not to purified, liver extracts given by mouth or by injection, and to yeast extracts administered by either route. This shows that it is not necessary for the responsible factor to come into contact with the gastric juice. Just before the War, attempts were made to isolate the factor from liver extract; and although it was established that riboflavin, pyridoxine, pantothenic acid and probably nicotinic acid are ineffective, no conclusive results were obtained, as the work was interrupted.

In opening the discussion on the afternoon's papers, Dr. F. Prescott suggested that synthesis of the vitamin B complex by bacteria in the intestine is not of great importance in man. Najjar and Holt gave aneurine in amounts greatly in excess of the physiological requirements and, when the experiments were repeated with smaller amounts, no evidence that the vitamin was excreted in the urine was obtained. Dr. Prescott suggested that the results of sulphonamide treatment are due not to inhibition of bacterial synthesis, but to direct interference with the respiratory mechanism of the body, simulating the effects of irradiation sickness and drug anæmia.

Speakers who took part in the subsequent discussion supported Dr. Platt's view as to the nutritional value of native-fermented liquors, and cited other examples of how native populations made good a deficiency of the vitamin B factors, for example, by drinking the contents of the rumen of freshly killed animals. The necessity for providing an adequate diet for the Colonial populations was stressed. The proceedings of the meeting were summarized by Dr. Harris, bringing to a conclusion a memorable meeting, which attracted a very large audience.

GENETIC TYPES OF MANGANESE DEPOSITS

A COMPARATIVE study of the manganese deposits of the U.S.S.R. by A. G. Betekhtin, based on intensive investigations carried out during the last few years, adds considerably to our knowledge of the conditions governing the formation of manganese ores (*Bull. Acad. Sci. U.R.S.S.*, No. 4, 3; English summary, 43; 1944).

Three groups of marine manganiferous sediments are distinguished:

(*a*) Most of the Palæozoic and Tertiary deposits are associated with siliceous and less common ferruginous chemical sediments, including radiolarian jaspers frequently accompanied by volcanic tuffs. The Tertiary ores of Chiatura, Transcaucasia and Polunochnoye, N. Urals, furnish typical examples similar to the classic deposits of Nikopol in the Ukraine. In the shallow-water facies formed near a shore of Cretaceous limestone, coarse pisolitic and massive psilomelane and pyrolusite occur. Farther out, the pisolites decrease in size, manganite becomes important and the silica and phosphorus contents increase. Still farther out, under conditions of oxygen deficiency, carbonates appear (rhodocrosite and manganocalcite) with glauconite, and there is marked enrichment in phosphates, sulphides and opal. Eventually the carbonates feather out and finally the ore-horizon is represented only by rare nodules of phosphorite.

(*b*) Deposits associated with calcareous sediments occur in the mountain ranges of west and central Siberia. They are mostly of late Pre-Cambrian age, but important occurrences are also found in the Cambrian of the Alatau. In the western Urals there are similar deposits of Permian age. The chief ore mineral in this type is manganocalcite.

(*c*) Deposits associated with clastic sediments are represented at Labinskoye in the Tertiary of the North Caucasus. Chemical sediments are absent and the ores (psilomelane, pyrolusite or manganese carbonates) occur as cementing material.

In regionally metamorphosed deposits, formed originally by sedimentation, anhydrous minerals are characteristic, for example, braunite and hausmannite, associated with magnetite and hæmatite and quartz. The waters liberated during metamorphism have given rise to veinlets which are mineralogically closely related to the enclosing rocks. Specific cases of this kind in Lower Carboniferous chemical sediments (siliceous and ferruginous) of Kazakhstan are described by Betekhtin and Suslov in the publication cited (pp. 86–99 and 100–108 respectively). Under conditions of more intense metamorphism, manganese silicates develop (rhodonite, spessartite, tephroite, piedmontite, etc.), and carbonate ores poor in silica form manganous marble. Here again, especially along belts of tectonic disturbance, migration and redistribution of manganese is indicated by the occurrence of veins and lenses of concentrated ore. These veins, though otherwise resembling hydrothermal deposits, are free from elements such as gold, silver, lead and zinc ; their origin is purely metamorphic. Vein and contact metasomatic deposits genetically connected with the hydrothermal activity of associated acid plutonic rocks are of far greater abundance and importance. The ores vary widely in composition and structure and often occur with a typical assemblage of sulphide minerals. In many of these deposits, however, there is evidence that the manganese compounds were not magmatic derivatives, but were taken from the manganiferous country rocks through which the hydrothermal solutions circulated.

All the above types of manganese deposits become secondarily enriched by weathering processes in the zone of oxidation, the end product being a pyrolusite-psilomelane complex. Betekhtin directs attention to the widespread development in the early stages of weathering of a manganic 'acid', H_2MnO_3, which occurs as dispersed colloidal particles (brown) or as colloform masses (black). Previously mistaken for manganite, this mineraloid is now distinguished as 'vernadite' after the geochemist Vernadsky, who originally predicted its discovery as a natural product. It is suggested that the various members of the psilomelane group may be salts of this acid. Concentration by chemical weathering is further intensified by the tendency of manganese hydroxides to migrate in colloidal solution and, activated by adsorbed alkali cations, to replace quartz and silicate minerals metasomatically.

ARTHUR HOLMES.

CHESHUNT EXPERIMENTAL STATION

THE Experimental and Research Station Cheshunt, Herts, has given a valuable lead the changing demands of war-time cropping of glasshouse industry. Discussion of problems relat to tomato and lettuce culture occupies all the ann report for 1943* and provides an index to the c centration of the industry upon food crops.

One of the most interesting items in the report the director, Dr. W. F. Bewley, is of trials of t Russian varieties of outdoor tomatoes. Stambo Alpatyev has a neat dwarf habit, bears fruit of g shape, scarlet and sweet ; it seems well worth furt trial. Bizon proved to be coarser, and gave ba shaped fruit, though neither variety was resist to frost exceeding two or three degrees. Two n varieties of lettuce, *5a* and *5b*, are being tested cc mercially ; they mature ten to fourteen days earl than Cheshunt Early Giant. One important expe ment with tomatoes involved the lowering of *p*H the soil by the addition of sulphur and sulphu acid. Sulphur, at the rate of 4 oz. per square ya gave only a slightly increased yield of fruit, but t soil, originally *p*H 8·79, was still *p*H 7·45 at the e of the season. Sulphuric acid caused the soil *p*H fall from 8·62 to 6·39 in a week ; but within a mon it had risen again to 7·84. It would seem that so upward movement of soil bases takes place. It fairly easy to make soil more alkaline, but it is not easy to render it more acid, and the results of a further work on these lines will be awaited wi interest.

An earlier annual report described resistance of t tomato varieties Riverside and Manx Marvel attack by the fungus *Verticillium albo-atrum*. Th does not now seem to hold under all cultural co ditions, according to P. H. Williams. I Selman has had a similar action of soil conditio in mind in his attempts to provide cultural facto which would enable tomato plants infected wi spotted wilt virus to carry a reasonable crop. Th should be a very practical approach to minimizi the damage caused by this disease, provided that it linked with adequate hygiene at the end of th season. Dr. Selman's work on this question is n very conclusive as yet, but his correlations of mosa infection and soil conditions with blotchy ripenin have given much more definite results. Unequ ripening seems to depend largely upon the wate retaining properties of a particular soil mixtur Steaming and the addition of peat without appropriat manurial adjustments, or the use of composts wit extreme fluctuations in water content, both favou the trouble, which is, moreover, always increased b mosaic infection. Mrs. Enid Sheard has investigate the pathology of tomato stem rot caused by th fungus *Didymella lycopersici*. The pathogen is mor virulent if it has wintered out of doors than a temperatures of about 59° F. Tomato seed does no seem to carry the fungus, and the only really sus ceptible alternative host so far discovered is th egg plant, *Solanum melongena*. Many organic sub stances allow saprophytic growth of the fungus which seems to grow best at a temperature of 20° C W. H. Read has tried many substances and treat ments for control, without much success, thoug ures containing salicylanilide give promise of ection upon the stems.

. R. Speyer, studying the red-spider mite, s that the application of top-dressings does not k infestation, and the use of petroleum emulsions ides the most practical control. The growth of at seedlings to act as bait for wireworm reduced r attack upon lettuce. O. Owen has investi- d the interrelations of various nutrient elements the tomato crop. Magnesium deficiency, for nple, is related to nitrogen, and iron to man- ese, while manganese and magnesium are ibly interdependent.

STRUCTURE OF BIOLOGICAL IBRES AND THE PROBLEM OF MUSCLE*

' is the mark of present-day biology that it looks ever more closely to "the Nature and Property of al Motion" of the actual molecules of structures, d it is from such a point of view that the problem muscle is again approached.

he physico-chemical mechanism of life is for the st part a manifestation of the forms and activities chain-molecules, chief among which are the pro- ns, which include myosin, now generally accepted the responsible contractile element of the muscle chine. X-ray studies show that myosin is a mem- r of a *family* of fibrous proteins to which belong o the keratins of hair, etc., the fibrous proteins the epidermis, and even fibrinogen and fibrin : all ese are characterized by a similar molecular plan d by similar long-range elastic properties that rest i changes of form of the molecules themselves. The ference is that muscular activity is a special case more general phenomena the full interpretation of hich implies an understanding of the properties and gnificance of the keratin-myosin-fibrinogen group s a whole.

The isolated proteins of this group—and this holds o for the myosin in living muscle—exist normally in state in which the polypeptide chains are in a egularly folded configuration, but they may be ulled out into an extended configuration that is wice as long, and they may also be 'supercontracted' nto more highly folded states. X-ray diffraction atterns of muscle, both living and dead, are throughut analogous to patterns that may be obtained from nammalian hairs, the 'supercontracted' state of the atter corresponding to the contracted state of the ormer. The outstanding common conclusion to be lrawn from these photographs is that shortening is not a question of simple disorientation of fibrils, but ather of folding within fibrils.

Thermodynamic tests show that entropy changes play only a minor part in the elastic properties of keratin and isolated myosin, from which it is reasonable to suppose, especially in the light of the X-ray findings, that the various states of muscle itself are also based fundamentally on the potential energy associated with states of folding of the myosin chains. It now appears from recent physiological evidence that such a concept does indeed promise to coordinate quantitatively the energetics of living muscle.

A detailed solution of the muscle problem will be reached only as part of the detailed elucidation of protein structure, studied against the background of other macro-molecules, such as the nucleic acids and polysaccharides, with which protein activity is so intimately bound up. X-ray analysis is now being supplemented by investigations with the electron microscope, and some of the evidence so obtained was presented.

* Substance of the Croonian Lecture delivered before the Royal Society by Dr. W. T. Astbury, F.R.S., on July 12

METER AND INSTRUMENT JEWELS AND PIVOTS

IN order to obtain a more fundamental knowledge of the phenomena relating to meter and instrument bearings and to improve such bearings, research has been carried out for a number of years on behalf of the British Electrical and Allied Research Industries Association at the Meter Testing Laboratories of the Northmet Power Company. A paper read by G. F. Shotter before the Institution of Electrical Engineers in London on May 4 gives a brief survey of the various aspects covered by this research, dealing mainly with the sapphire/steel combination but including other combinations of materials.

The apparatus and methods of test are outlined, followed by a survey of the results from life-tests, including an analysis of the various factors which contribute to wear. The results of a microscopical examination of the units at the end of their life-run are discussed. A brief theory of the boundary lubrication existing in such bearings is given, with a short extract of the detailed discussion of the various factors contained in E.R.A. Reports.

The results of experiments on the resistance of sapphire jewels to impact forces are given; and the phenomena associated with bottom bearings at various loads, caused by parasitic forces existing in meters, are also dealt with. The actions of the ball-type bearing and that of the pivot bearing are compared, and an approximate estimation of the life of bearings in practice, based on life-tests, is made.

A brief summary of the general conclusions reached during the tests is as follows. (*a*) Metals so far tried as alternatives to steel for pivots are in no way superior. The best material tested was osmium-rhodium, which gave good results in the dry as well as the lubricated condition. (*b*) With the exception of osmium-rhodium and possibly natural zircon (90°), the substitute materials tested, particularly glass, proved useless in the dry condition. (*c*) Various forms of oxide were produced, each having its own characteristics; one or two appeared to be self-lubricating. (*d*) The initial friction of substitute materials was generally higher than that of the steel/sapphire units. (*e*) With the exception of diamond, the substitute materials tested generally show a higher coefficient of friction than the steel/sapphire units. (*f*) The range of penultimate/ultimate test values of friction shows considerable variation. Some materials, for example, natural zircon (90°), show a lower value than that of steel/sapphire. Other units, notably glass, give extremely high values, particularly in the dry condition. (*g*) The type of wear area formed depends on the structure of the materials under test. Homogeneous and amorphous materials normally give circular wear.

FORTHCOMING EVENT

Tuesday, July 24

Quekett Microscopical Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Conversation and the Exhibition of Specimens.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Principal of the Gainsborough County Technical College—The Director of Education, County Offices, Lincoln (July 30).

Engineering Assistant—Mr. P. Wilkinson, Staffordshire Potteries Water Board, Engineer's Offices, Albion Street, Hanley, Stoke-on-Trent, endorsed 'Engineering Assistant' (July 30).

Lecturer in Chemistry—The Secretary, The University, Edinburgh (July 31)

Agricultural Economics Officer in the Ministry of Agriculture, Government of Northern Ireland—Assistant Secretary (Establishments), Ministry of Finance, Stormont, Belfast (July 31).

Assistant Lecturer in Social Science (Grade III)—The Registrar, The University, Liverpool (July 31).

Senior Electrical Engineer for Middle East (in connexion with Oil Pipe-line Construction and Operation)—The Ministry of Labour and National Service, Appointments Department A 9, Room 670, York House, Kingsway, London, W.C.2, quoting D.1292.XA (July 31).

Scientific Assistant (temporary) on the Staff of the Department of Agricultural Economics, Bristol II Advisory Province, Newton Abbot—The Secretary and Registrar, The University, Bristol 8 (July 31)

Demonstrator (man) in Chemistry (should possess a good Honours Degree, and have special qualifications in Organic Chemistry)—The Secretary, King's College, Strand, London, W C.2 (July 31).

Junior Engineering Assistant—The Waterworks Engineer and Manager, Civic Centre, Southampton (August 3).

Civil Engineering Assistant—The Engineer and General Manager, Tees Valley Water Board, Water Board Offices, Corporation Road, Middlesbrough, endorsed 'Civil Engineering Assistant' (August 4).

Scientific Glass Blower for Division of Industrial Chemistry, Melbourne—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, York House, Kingsway, London, W.C 2, quoting Ref. 4239 (August 4).

Assistant Lecturer (temporary) in Mathematics, and an Assistant Lecturer (temporary) in Metallurgy—The Registrar, University College, Singleton Park, Swansea (August 7).

Chief Nutrition Officer, Ruakura Animal Research Station, Hamilton, New Zealand—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (August 10).

Secretary-Editor—The Acting Secretary, The Museums Association, Chaucer House, Malet Place, London, W.C.1 (August 10).

Research Officer in Theoretical Physics, Division of Industrial Chemistry, Council for Scientific and Industrial Research, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C 2 (August 11)

Academic Adviser (man or woman) for Tutorial Classes—The University of London Extension Registrar, c/o London School of Hygiene and Tropical Medicine, Keppel Street, London, W C.1 (August 15)

Lecturers (2) in Mathematics (one Lecturer must have special qualifications in Applied Mathematics and Mathematical Physics)—The Secretary, The University, St. Andrews (August 18).

Assistant in Zoology in the United College, St. Andrews—The Secretary, The University, St. Andrews (August 18).

Readership in Engineering Science—The Registrar, University Registry, Oxford (August 20)

Lecturer in the Department of Electrical Engineering—The Registrar, The University, Sheffield (August 31).

Demonstrator in Physiology—The Registrar, The University, Liverpool (August 31).

Pathologist in the Giza Memorial Ophthalmic Laboratory, Cairo—Sir Holburt Waring, Bart, Pen Moel, Tidenham, Chepstow, Mon. (August 31).

Lecturer, and an Assistant Lecturer, in the Department of Physics—The Acting Registrar, The University, Leeds 2 (September 1).

Professor of Dentistry and Director of the Dental School in the University of Otago—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 15).

Lecturer to lecture and undertake researches on Freshwater Zoology, and to assist in the general teaching of Zoology, and a Lecturer to assist in the general teaching of Zoology—The Registrar, The University, Liverpool (September 19).

Chair of Surgery tenable at the British Postgraduate Medical School—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (January 1).

Director of the British Non-Ferrous Metals Federation—The Secretaries, Messrs. Peat, Marwick, Mitchell and Co, 18 Bennets Hill, Birmingham 2, endorsed 'Federation Selection Committee'.

Principal in connexion with the training of Ex-Servicemen at the Wiltshire Farm Institute—The Chief Executive Officer, Wiltshire War Agricultural Executive Committee, Agricultural Department, County Hall, Trowbridge, Wilts.

Principal's Secretary (woman)—The Principal, Studley Agricultural College, Studley, Warwickshire.

Graduate in Physics, with Pure and Applied Mathematics, a Graduate in Chemistry with Final Physics, and a Graduate in Engineering with expert qualifications in Engineering Drawing—The Principal, Mining and Technical Institute, Neath, Glam.

Assistants for (a) Mathematics, Engineering Science a lated Subjects, (b) Engineering Drawing, Engineering S and related Subjects, (c) Workshops—Machines, Fitting, Wel The Principal, County Technical College, Dartford, Kent.

Lecturer in Inorganic and Physical Chemistry—The Pri Medway Technical College, Gillingham, Kent.

Domestic Science Instructress for work at the Trow Victoria Technical Institute and in connexion with Adult Cla The Deputy Director of Education, County Hall, Trowbridge,

Teacher of Engineering Drawing, Engineering Sc Practical Mathematics, Workshop Technology, Jig and Drawing and Design to ordinary National Certificate stand the Redditch Technical School—Mr. G. Brodrick, Education Church Green West, Redditch, Worcestershire.

MORALE IN INDUSTRY

IN the subscription by people of all political parties in Britain to the policies of full employment and a rising standard of living, far too little has been said of some of the practical implications of these aims. There is indeed general agreement that total spending must be maintained at a high level, investment in industry scaled up, research encouraged, the quality of management improved and monopolistic restrictive practices rooted out. But it is rare to find any reference to another, and no less indispensable condition, both on economic grounds and by its bearing on the morale of the whole community: namely, the organization and incentives of industry must be so contrived that individual men and women produce as much as they can, putting no limit, conscious or unconscious, on reasonable maximum output. After five years of intense effort and overstrain, it is natural that everyone should look for shorter hours and increased leisure, but it is imperative to realize that in a world so short of consumption goods, houses, and utility services and amenities, the maximum output must be forthcoming during these shortened hours of work.

This is, in fact, part of the price to be paid for social security, but it is rare indeed to find the full implications of industrial efficiency, where they touch the worker himself, recognized; and the broadsheet "Output and the Worker" issued by P.E.P. expounds an aspect of the drive for full production which the dust of the general election in Britain has tended still further to conceal. The causes of limitation of output go deep and involve a complex of mental and physical factors. Lighting and ventilation, and other sources of physical comfort or discomfort, have an obvious effect on output; but the effect of mental factors such as the fear of unemployment and anxiety about pay may be equally important though less obvious.

The P.E.P. broadsheet, which is based on part of a forthcoming report on industrial relations, and compares the main findings of qualified investigators on this subject, suggests that security of employment alone would remove one of the main brakes on individual or group production. Again, it suggests that production committees, wisely handled, should go some way towards removing another mental obstacle to full production—the sense of antagonism between workers and management, arising from a real or supposed clash of interests. At the same time, by spreading a feeling of greater personal responsibility, these committees might help to mitigate industrial boredom, itself a potent source of restriction.

There is no simple cure for these and other mental causes of restriction, nor can the problem as a whole be tackled successfully by management alone. A joint approach by management and workers is required, and a reconciliation should be sought between their group interests. The broadsheet affords strong support for the view advanced by Prof. H. J. Laski in his "Reflexions on the Revolution of our Time", that with the achievement of a policy of full employment the trade unions may have new and more positive functions in place of those defensive and sometimes restrictive policies which they have pursued in the past.

The evidence reviewed by P.E.P. in this broadsheet covers experience in the United States, including that of M. E. Dickson, of Whiting Williams, of S. B. Matthewson and the prolonged researches at the Hawthorne Works of the Western Electric Co. in Chicago, as well as the work of S. Wyatt, H. M. Vernon and the well-known series of studies under the Industrial Health Research Board in Britain. Restriction in particular is closely analysed by S. B. Matthewson in "Restriction of Output Among Unorganised Workers", and more recently by F. J. Roethlisberger and W. J. Dickson in "Management and the Worker" (Harvard University Press, 1942).

The present P.E.P. broadsheet is concerned with what may be termed the predominantly mental sources of limitation of output, whether conscious or unconscious. Physical factors, such as lighting, heating, ventilation, humidity and noise may diminish or increase physical fatigue and so affect output. But while bad conditions in respect of any of these factors may reduce output severely, even if conditions are reasonably good further changes in the physical environment may have little effect by comparison with psychological factors which may mask any effect due to the physical factors. It is of course difficult to draw a firm distinction in practice between fatigue and boredom. Physical and mental factors in practice usually interact, and the brilliant investigations of the Industrial Health Research Board into the nature of industrial boredom and its effect on output, which as a result of the increasing importance of repetitive work in modern factory-production has become one of industry's most pressing problems, have indicated that the attitude to work is largely a group phenomenon. Working groups tend to have a predominating tone in this respect, and this tone frequently depends on one or two outstanding personalities, acting as more or less informal leaders to the group.

Similarly, it is difficult to distinguish conscious from unconscious elements, and unconscious or semi-unconscious limitation of output is probably more prevalent than deliberate, organized limitation. That factor in itself may well have had an important influence on the high level of output during the summer and autumn of 1940, and have masked to some extent the injurious effect of the excessive hours worked during a prolonged period in spite of all the evidence of the dangers of such a policy. Fear of unemployment undoubtedly ranks high among the causes limiting output, and so long as mass unemployment is allowed to occur, the widespread belief will persist that there is a definite limit to the amount of work to be done, and that it is therefore in the interest of wage-earners as a whole to share what work is available among as many people as possible. Such reasoning will not be rooted out by mere argument, and there have already been incidents in the transfer of labour from war-time employment which, to say the least, will not help such eradication.

Matters affecting payment, particularly fea rate-cutting, come next in importance; but w the case against economic factors as a main caus restrictive practices may possibly be over-stated Roethlisberger and Dickson, here as in boredom a matter of physical and mental factors interact Moreover, though a new machine or an improvem in technique could probably have more effect on duction than could any improvement in app industrial psychology, the absolute contribut which could come if we achieve the highest product potential of working individuals and groups is v great. In addition, when the majority of its memb are deliberately or unconsciously giving less th their best, a society is on a very unsound basis.

For these reasons, an improvement in industr morale stands only second in importance to impro ment in industrial technique and equipment. In sp of its defects in morale, industrial efficiency in Brit suffers more from lack of up-to-date equipment a organization than from lack of skill in its operative but as we replace obsolete methods and equipme and approach American standards, the importance morale will increase. Experience of the industrial w effort in Britain, the United States and the U.S.S. suggests that utilization of the group interest of t workers themselves is the most important line advance, and clearly offers great scope for c operation between management and trade union So long as there is a real or supposed gap between t group interests of workers and management, th enlisting of this source of productive energy w remain imperfect, and in spite of the valuable lesso to be learnt from the war-time joint productio committees, the scope of such bodies has yet to b worked out in its most effective form.

It must be recognized that there are genera features of the industrial situation, independent o trade unionism, which are of governing importance The total economic situation, as already emphasized profoundly affects the industrial psychology of the working individual or group. Again, mechanisms o defence which the average worker erects against the trade cycle and the attitude that goes with them persist even when not relevant in a given economic situation. Then there is a long-standing and deep seated suspicion of authority in all its forms, and particularly as seen in the supervising staff in immediate contact with the worker.

To these features the P.E.P. broadsheet makes no more than passing reference, although their importance is clearly stressed. The central difficulty, however, is nowhere stated in the broadsheet, for all the recognition of the value and the limitations of scientific research in this field. That difficulty is essentially the inevitable opposition which develops between the scientific approach to the human problems of production and the political approach of the administrator trained in the method of accommodation and compromise. The balancing of opinions and the compromise of different points of view, which is the essence of the political process, may be totally at odds with the scientific approach to questions of industrial management. What is required is not the render of scientific principles of accepted accuracy, the ignoring of established fact, but the combina- n or integration of both the political and the entific approach in a solution which satisfies both e scientific and the psychological or political quirements.

On our success in achieving such a solution, the estion of morale, industrial efficiency and ultimately full employment policy largely depend. The point uld scarcely have been made better than in the dress "Compromise and Integration" which Colonel Urwick delivered last February to a joint meeting Liverpool of the Institute of Labour Management d the Institute of Industrial Administration. The conciliation of our institutions to the new environ- ent created by science and technology is the great roblem of our civilization, and Colonel Urwick emonstrated effectively the challenge involved in sing fully the results of scientific knowledge and the mense control it gives us over material things, ithout sacrificing the freedom of mind which alone akes further scientific progress possible.

Not the least significant part of Colonel Urwick's ddress is the opening part, in which he stresses the eed for precise thinking and for exactness in the use f words. Words are the tools with which men think, nd scientific workers would be more effective in the nterpretation of their work to the community if they cept that axiom more constantly in mind. In any vent it must be regarded if we are to achieve the ntegration of scientific workers and technicians with each other, and of science and technology with the life of the community. A first step to the new kind of thinking, towards seeing our problems as a single problem, to the integration which will eliminate the confusion into which our civilization has fallen since the industrial revolution, is a clear understanding of the words we use as our tools of thought, and in particular of the distinction between compromise and integration. It is also the first step towards resolution of the conflict between social classes and between private ownership and State bureaucracy.

While a clear understanding of the terms used is a first essential, the light of a great common purpose alive and real in the minds of all the specialists as in that of the community they serve is equally important. Such a purpose must be conceived in terms of the common welfare, not in that of a particular class or section; and of its nature it implies the participation of all the people for its realization. Such participation in its turn demands not just that the experts understand each other, but that they make their specialized tasks explicit to the people, so that they are understood by and become real to them.

This is impossible, as Colonel Urwick points out, while men try to live their lives in water-tight compartments guided by mutually incompatible principles. We must, he reminds us, restate our philosophy of economic life in terms which can give both specialists and workers a sense of common moral purpose. To do this, to integrate the real wishes of the right and of the left in Britain, we need vision and determination to cut through the verbal formulations, the truculent attitudes, and the clinging to outworn slogans in which those wishes are disguised. Our national spirit of accommodation and conciliation should be exercised in making conflict really constructive, and in inventing and developing true integrations.

The significance of all this in industrial psychology and in management generally, and the challenge offered to constructive thought by the present situation, should need no further emphasis for the scientific worker. But if industrial efficiency and the achievement of the maximum output require a closer integration of the workers and of the management, equally they require a closer integration of industry itself with the needs and purposes of the community as a whole. That will not be achieved merely by scientific research in the field of industrial health and psychology, by the establishment of the most effective conditions for joint production committees, and so on. It is part of the larger task of establishing the dynamic relations between individuals and the organizations they serve in the nation as a whole which really represents what we understand by the term 'morale'. For this we need to call on the civic idealism and spirit of service which the Fighting Forces have already generated in youth. In the schemes for education in citizenship, study circles, discussion and community groups, supported by such national services as the Arts Council of Great Britain, and possibly a national fellowship of service as suggested by Mr. Arthur Bryant, we may be able to elaborate machinery through which democracy can function on the ground-level, and the spirit of accommodation and reason be fostered as against an uncompromising attitude which is so grave a danger to industrial efficiency and to the existence of democracy. Ultimately, industrial efficiency depends on the integration of the purposes of industry with those of the community itself; and for the smooth functioning of our co-operative institutions, whether industrial, professional or cultural, the preservation of their social values, and the establishment of dynamic relations with the community they serve, not merely technical knowledge but also the skilled diagnosis of human situations are vital factors.

TROPICAL PEDOLOGY

The Soils of Equatorial Regions

With Special Reference to the Netherlands East Indies. By Prof. Dr. E. C. Jul. Mohr. Translated from the Nederlandsch by Robert L. Pendleton. Pp. xii+766. (Ann Arbor, Mich.: Edwards Brothers, Inc.; London: H. K. Lewis and Co., Ltd., 1944.) 7.50 dollars.

THE study of soils in equatorial or tropical countries has been very backward in comparison with that in temperate regions in spite of the great development of agriculture in the low latitudes. What is known is largely due to agricultural officers and chemists who had little time to spare from their routine duties. Unfortunately, much of the information available is for surface soils only, profile studies being rather scarce. Comprehensive studies on tropical soils are thus rare, and one turns with interest to the volume under review for enlightenment on the many pedological problems provided by these soils.

The book begins with an extensive description, with chemical analyses, of most of the rock types occurring in the Netherlands East Indies. The second chapter passes naturally to a consideration of "the active forces of soil formation", that is, climate, both atmospheric and soil. Chapter 3 is devoted to a discussion of the processes of weathering and soil development. The remainder of the volume consists of descriptions of the geology, soils and agriculture of the islands composing the Netherlands East Indies.

In 1930 Dr. Pendleton first made available in English Dr. Mohr's theories of tropical soil development, to which little attention has been paid by soil workers. In a way, this is not surprising, for the symbolic method used by Mohr for soil description is repellent at first sight; for example, one soil discussed has the following designation

$$V(a + b) . (1 + 2) - Ma.NN.ae.3.$$

The various factors represented in this notation and which form the basis of the discussion are parent material, temperature zone, water movement in the soil, whether weathering is aerobic or anaerobic, and finally the stage in the developmental series. In illustration we may give briefly Mohr's conception of the formation of a laterite soil from a basic volcanic ash in tropical lowland; the soil sequence is symbolized as $V.b.1 - He.NN.ae.$ (1–5). The first stage is the leaching of bases and silica, the latter precipitating at depth to form a tuff which gradually leads to the development of a perched water-table. From the upper layers silica continues to be lost and soon kaolin follows, leaving behind iron oxides, alumina and quartz. The iron oxide gradually ages and the colour of the soil changes through yellowish brown to red, with mottling in the lower parts. Within the water-table the iron rises and is deposited in the form of a pan or crust when it comes in contact with air. This results in its separation from the kaolin. The water-level is gradually raised, the ferrugmous layer is moved upwards and the kaolin layer becomes thicker. Eventually the eluvial layer becomes impoverished of silica and kaolin and there is then a differentiation of the iron and aluminium into two layers, the aluminous one being the lower. With soil impoverishment the soil vegetation deteriorates and erosion increases so that the ferruginous layer becomes exposed as a crust. At higher elevations the whole process is much slower and erosion so much greater that if red earths are found, it is assumed that they are really fossil, having been formed near sea-level and afterwards raised to their present position by tectonic movements.

Mohr's analysis of the development of a laterite soil is similar to that given by Campbell in 1917. Later, on the basis of his studies in the Amazon Basin and Cuba, Marbut (1930) showed this particular soil to be a type owing its existence to a high ground water-table, and not at all typical of well-drained sites. From Mohr's account one gets the impression that this ground-water type is the only one occurring in the Netherland East Indies, but since well-drained laterite soils with no ferruginous horizon as visualized by Mohr have been repeatedly described in the Far East (China, Ceylon, the Philippines) it would be strange if none occurred in these islands.

Although the scheme is worked out in detail o for volcanic ash deposits, it should be applical perhaps with minor modifications, to soil devel ment on other rocks, for example, granites, gabbr etc. From Mohr's own descriptions it is quite i possible to tell to what extent it does really app The sole criterion used in later parts of the book i establishing the stage of development seems to the colour of the eluvial layer, that is, whether it grey, yellow or red. The nature of the parent materi of course, does affect the rate of development a Mohr states that basic igneous rocks give redo 'lixivia' than granites, which tend to give yellow 'lixivia' although they may become red. Develc mental series similar to the above example are al worked out for other parent materials, such as ma and limestones, and for other drainage conditio for example,[1] impeded and imperfect, the associat soil types including black earths and terra rossa.

The principal value of Mohr's method of classific tion is that it emphasizes the idea of development sequence which is too often ignored in soil studie It may thus provide a clue to the interrelationsh of the red and yellow lateritic earths which are bot quite well established now, but the position of whic in the general scheme of soil classification is not y clear.

The part played by organic matter in tropical so formation is given great prominence and the proble of erosion is fully discussed. In the discussion (erosion, Mohr emphasizes the effect of the differen forms of hydrous iron oxide on erodability of soil In the colloidal state there is mutual flocculatio between the iron oxide and clay and organic matte resulting in a pervious system. When, however, th iron oxide is more highly crystalline (gœthite o hæmatite) it does not have a flocculating effect o the clay. When the latter "is poor in bases it i excessively dispersed hence impervious to air and water". Thus juvenile brown earth is pervious, but when saturated with water quite easily erodable. Senile red earth is more difficultly permeable and is less subject to washing off. With alumina the theory is similar. Thus, soils with a low silica-sesquioxide ratio, that is, soils of the warm humid regions, are non-erosive if iron oxide occurs in one or other of the red forms. With regard to the relatively high values reported for organic matter in red and yellow tropical soils, Mohr doubts their accuracy, and suggests that they may be due to carbon dioxide adsorbed on the abundant hydrous iron oxide present in the soils and not to organic matter.

In the second part of the book, a section is devoted to each of the islands or territories under Dutch control. The material in each section includes a brief discussion of the geology, weathering conditions and soil formation, finishing with a description of the agriculture in relation to soils. This part will be of greater interest to agriculturists concerned with tropical crops, and it seems to give a good account of the various practices, with suggestions for improvement.

From the pedological point of view, the main weakness of the book is the virtually complete lack of either adequate profile descriptions or chemical analyses which might substantiate Dr. Mohr's theories. Any theory of tropical soil development must take into cognizance available data from other countries, and this Dr. Mohr has failed to do. There is no reference to the work of Hardy in Trinidad, Joachim in Ceylon, Martin and Doyne in West Africa, American studies in the Caribbean and Pacific ions, although Harrassowitz comes in for strong ticism. The book also suffers somewhat from the t that its original production was protracted 33–38), so that one finds in the earlier part, for ample, that 'kaolin' is the main component of e clay of the various soils, while in later sections ontmorillonite' takes its place in discussions of e black earths and terra rossa. There are many her points on which the book might be criticized, t this would be unfair since the author was unable complete the projected revision for the English ition.

Dr. Pendleton has made an excellent translation der considerable difficulties, and the book is well istrated and beautifully produced; but I would ich rather have seen an account of tropical soil mation by Dr. Pendleton himself, for few soil rkers have had such a long and varied experience these soils.

A. MUIR.

STUDY OF EARTHQUAKES

eismology
y Perry Byerly. (Prentice-Hall Geology Series.) p. x+256. (New York: Prentice-Hall Inc., 1942.) .65 dollars.

THIS book about earthquakes and their study, by an eminent American professor, living in a tate occasionally visited by strong earthquakes, and eaching seismology in a university which introduced he subject to the United States, is a valuable, important and welcome addition to international eismological literature. The book is divided into wo parts. The first seven chapters, Part 1, are on he subject of earthquakes and require little technical nowledge. Part 2, entitled seismography, preupposes readers with some preparation in mathematics and physics.

Many perfectly general problems in seismology have already been solved. Excellent summaries of the main theories of earthquake causes at present tenable are given in Chapter 4, while many others have been discarded as quantitatively unreasonable. The author admirably stresses the living nature of the subject and often the reader's imagination is kept alive, and his feet on solid unshaking rock, by queries about the theories (pp. 50–51). A start only has been made with the details of seismology; for example, Prof. B. Gutenberg and others have discovered local variations in the travel-time tables (pp. 210–14) and thus have suggested answers to geophysical questions concerning mountain roots—and the subject bristles with topics for research. Not one of the theories listed in Chapter 4 will enable one to decide in advance the exact focus and time of occurrence of a shock, and it is just these things which engineers and public authorities wish to know if they are to take all precautions for public safety. Can instruments be devised to detect variations in critical material deep underground such as accumulating pressure or variations in temperature and plasticity? It is to details such as sudden changes in these and like functions to which we must look. There are also minor discrepancies in seismology to clear up, such as the differences occasionally met with between mathematically determined epicentres (from readings of seismograms) and the same epicentres determined geologically in the field (p. 26). The old problem, however, of distinguishing cause and effect as between earthquake and geological fault is considered solved by Prof. Byerly, who says (p. 26), "On the whole it seems reasonable in our present state of knowledge to assign *faulting* as the *cause* of all large earthquakes and almost all small ones". A four-figure number is suggested for each earthquake, each successive figure denoting intensity, greatest perceptible distance, lives lost, and damage to property. Such a number would describe the shock in greater detail than the present Modified Mercalli Scale number only. Such suggestions are extremely important in areas comparable with California, where an extensive programme of research is carried out by the United States Coast and Geodetic Survey with the co-operation of thousands of observers.

It is well known that world maps on which are placed dots for earthquake epicentres show definite lanes within which most of the earth's recent earthquakes have occurred. Most seismologists wish to show more than this in a manner which is as little complicated as possible. From time to time various suggestions have been made as to what else to include. Such quantities as intensity and depth of focus have been mentioned, but Prof. Byerly prefers 'seismicity' which includes area shaken, intensity and frequency. This he evaluates for areas in California (map p. 86). Part 1 ends with some new material on a few of the world's great earthquakes.

Part 2 opens with an excellent chapter of forty-eight pages on the mathematical theory of modern seismographs. Most of this space is given to the derivation of the fundamental equations of motion. The operational method for the solution of differential equations is first used to obtain the general equation of the response of a seismograph to an earth acceleration Φ. Free pendulums and damped pendulums are then examined with particular types of Φ. The determination of the constants and the dynamic magnification are dealt with, as is also electromagnetic registration for such as the Galitzin type seismograph. Some notes are given on the Benioff type in which an iron core or armature is used with the coil, on types of suspension and on methods of recording and damping.

Very little space is devoted to the all-important subject of time-keeping, though perhaps it is thought that this deserves a volume to itself. The mathematical theory of elastic waves is covered in twenty-six pages. General equations of motion, waves, reflexion and refraction, Rayleigh and Love waves are examined, and there is a paragraph concerning observations on surface waves. Paths of waves and travel-time curves are dealt with first mathematically in an idealized way and then practically and observationally. There follows naturally a short chapter on the location of epicentres by instrumental methods. The last chapter, on seismograms, covers in a masterly way modern trends from the shaking table experiments of K. Dyk and the analysis of seismograms by integration to the idealized mathematical work on the dispersion of Love and Rayleigh waves.

In so short a book for so wide a field one feels that the author must have had some anxious times pondering what to leave out. Not all topics have been touched upon, and the lists of references at the ends of the chapters have omissions even in the topics discussed in the chapter. It may still be true that there is no royal road to learning, but this book will undoubtedly form a good and sound though limited 'air landing strip in the kingdom of seismology'. From this strip the applied mathematician or mathematical physicist could easily range the seismological field and find suitable targets for attack with his mathematical weapons. The book would be most useful to university teachers of these subjects who are in search of problems for their advanced and research students. In this case chapter 1 and part of chapter 2 could be omitted.

The format is very pleasing and the printing is bold. The line diagrams are good but the reproduction of the photographic illustrations might be improved in a later edition. There is an adequate index.

E. TILLOTSON.

TEACHING OF PHARMACOGNOSY

A Text-Book of Pharmacognosy

By George Edward Trease. Fourth edition revised with the assistance of Dr. H. E. Street and E. O'F. Walsh, with Contributions by Dr. R. Bienfang, H. M. Hirst, H. O. Meek and A. H Ware. Pp. viii+800. (London : Baillière, Tindall and Cox, 1945.) 27*s.* 6*d.*

MR. TREASE can justly claim to be one of the foremost exponents of pharmacognosy in Britain. His work at Nottingham is well known, where he is head of the Department of Pharmacy and responsible for the teaching of pharmacognosy. He is also an examiner in this subject for the Pharmaceutical Society and for the University of London.

Teachers and students will welcome this fourth edition of an already well-used text-book, and those familiar with the previous editions will readily recognize the improvement brought about by a complete revision of the subject-matter. Mr. Trease has gone to considerable pains to incorporate, up to the time of writing, the results of recent research, and also the material the use of which in medicine has been permitted owing to the exigencies of war. The result is a volume packed with useful information presented in an attractive manner and profusely illustrated.

One of the major alterations is the extension of the chapter on cell-structure. To his credit, Mr. Trease has not hesitated to draw upon those who have special knowledge of different aspects of his subject. A good working knowledge of plant histology is essential to success in the higher branches of pharmacognosy, where microscopy is so important in the identification of drugs in powder form. Many students have to approach it equipped only with the botanical training of the standard required for the Pharmaceutical Society's Intermediate Examination. Such students do not extend their knowledge of plant structure in further botanical work except as afforded by pharmacognosy. Teachers of this subject are therefore compelled to devote considerable time to plant histology. Therefore Dr. Street's account of cell-structure, and his well-executed drawings illustrating various types commonly met with, will be much appreciated.

It is questionable whether, with his limited botanical knowledge, the student can appreciate the arrangement of the official drugs of vegetable origin according to the systematic classification of plants. For teaching purposes it appears to be more convenient to classify the drugs themselves according to their morphological nature. Such arrangement enables the student to compare and contrast similar organs both macro- and microscopically and to member more easily the points of difference diagnostic purposes. One advantage of the pres arrangement is to emphasize that similarity of che ical constituents in drugs does not necessarily im close phylogenetic relationship.

The publishers are to be congratulated on hav been able to produce a work of this magnitu relatively free from errors, under war-time restrictio of labour and materials.

W. O. HOWARTH.

ADVANCED ORGANIC CHEMISTR

Organic Chemistry

By Louis F. Fieser and Mary Fieser. Pp. xii+10 (Boston : D. C. Heath and Co., London : George Harrap and Co., Ltd., 1944.) 30*s.*

WITHIN the limits of this treatment the auth have undertaken a survey of the vast field organic chemistry at the level of students readi for an honours degree in the subject. This ambitio project has been carried through with conspicuo success in a single volume of forty chapters and little more than a thousand pages. The book written in a clear and easy style, flowing natural from one topic to the next. The dual authorship so effective that it shows little sign of the numero joints indicated in the preface ; nor would the read suspect, apart from the statement in the same plac that a large part of the writing of the senior auth was done "in trains, planes, hotels, and army cam in the course of more than one hundred trips".

Starting with hydrocarbons and alcohols, th account leads through other common aliphatic type to Chapter 11 on stereochemistry. Following thi chapters on ring formation, rubber, carbohydrate fats and waxes, and proteins, are succeeded b specialized reviews of microbiological processes, th role of carbohydrates in biological processes, and th metabolism of fats, proteins and amino acids. Th next thirteen chapters are devoted to aromati chemistry, and the work ends with further chapters o dyes, synthetic fibres, synthetic plastics and resins steroids, isoprenoid compounds, accessory dietar factors, and advances in chemotherapy.

The work affords a valuable and up-to-date treatment of organic chemistry, in which due stress is laid on technological, biological and medical aspects of the subject. Modern theories of organic chemistry are well developed as the book unfolds, and this object has been achieved unobtrusively without an undue display of electronic symbolism to delay the narrative or obfuscate the reader. The text is well documented with a list of reading references at the end of each chapter ; there is a good index ; and the letterpress, diagrams and formulæ are admirably printed. An unusual feature is the statement of the yields obtainable in many of the reactions quoted. With so much to applaud, it would perhaps seem ungracious to suggest that more space could have been allocated to one specific theme at the expense of another—as, for example, to terpenes at the expense of aromatics—but it is difficult to advance any other criticism of moment. Taking it all in all, this work provides one of the best surveys of organic chemistry to be produced in recent years for advanced students of the subject, and it is bound to achieve popularity among this overburdened section of the modern community.

JOHN READ.

LUBRICATION OF METAL SURFACES BY FATTY ACIDS

By Dr. F. P. BOWDEN, J. N. GREGORY
AND
Dr. D. TABOR
ouncil for Scientific and Industrial Research, University, Melbourne

WHEN surfaces in relative motion are separated by a fluid layer of appreciable thickness, the sistance to motion is due to the viscosity of the terposed layer. This type of lubrication is essentially problem in hydrodynamics; the friction is very nall and there is no wear of the moving surfaces. is clear, however, that in many practical cases uid lubrication is impossible. In many sliding echanisms, or at the beginning and end of a ciprocating stroke, it is difficult for a thick conuous film of lubricant to be maintained, and even rotating parts the thick film may break down and ly a thin film of lubricant may remain. In such ases the friction is influenced by the nature of the nderlying surfaces as well as the chemical conitution of the lubricant, and Hardy referred to such state as 'boundary lubrication'. Boundary lubricaion is of great importance in practice, and the nature f the surface film will determine whether serious wear or seizure will take place. The coefficient of riction for really clean metals which have been outgassed in a good vacuum is high and may be[1] about $\mu = 6$. For ordinary unlubricated metal surfaces which are exposed to the air the coefficient of friction s of the order of $\mu = 0{\cdot}5$–1. For metal surfaces ubricated with a boundary film μ is about 0·05–0·15. This is considerably less than for clean surfaces, but s much higher than for fluid lubrication.

Effect of Chain Length

A systematic investigation of boundary lubrication was first undertaken by Hardy[2], who measured the static friction between surfaces, using homologous series of paraffins, fatty acids and alcohols as the lubricants. Using simple apparatus, he found that the coefficient of static friction decreased linearly with the chain-length of each family of compounds. The friction also depended on the nature of the underlying solid surfaces. He was thus able to show that the friction was a function of separate contributions by the solid surfaces, the chemical series to which the lubricant belonged and the number of carbon atoms in the chain.

Hardy explained these results by a very simple and elegant theory. He assumed that the friction between unlubricated surfaces is due to the surface fields of force. When the lubricant is added, the lubricant molecules orientate themselves at each of the solid surfaces to form a unimolecular adsorbed film. The solids sink through the lubricant layer until they are separated by only the unimolecular adsorbed film of lubricant. Slip then takes place between these adsorbed films, and the efficiency of a boundary lubricant is measured by the extent to which these films can mask the fields of force of the underlying surfaces. Along these lines Hardy was able to explain the linear relationship observed between the friction and the molecular weight for different members of a homologous series.

Later workers on static friction have not, however, fully confirmed these results[3]. Measurements of *kinetic* friction[4] also show that for a given homologous series there is no linear relation between friction and chain-length, but a fairly rapid decrease in the coefficient of friction, μ, to a constant value of about 0·1 as the chain-length increases. With fatty acids this steady value of μ is reached for steel surfaces when the molecular weight exceeds about 100, and for glass surfaces when the molecular weight exceeds about 200.

If the friction is measured with an apparatus in which one of the sliding surfaces possesses an appreciable degree of elastic freedom, the motion may not be continuous but may proceed in a series of jerks. There is an intermittent clutching and breaking away of the surfaces, and the friction, surface temperature, and the area of contact all show violent fluctuations. The nature and extent of these fluctuations naturally depend upon the elastic and mechanical properties of the system, but for given conditions the nature of the motion is profoundly influenced by the nature of the surfaces themselves[5]. With unlubricated metals and other solids, the surfaces are always torn to an appreciable extent and it is clear that the friction cannot be regarded entirely as a surface effect, but must be closely dependent upon the bulk properties of the solids. With mineral oils and many other lubricants the friction is lower, but the behaviour may still be essentially the same as for unlubricated metals. The intermittent clutching and breaking away still occurs through the lubricant films, and marked wear of the surface may still occur. Certain substances, however, are able to prevent this 'stick-slip' motion and allow smooth sliding to take place.

This type of measurement may be used to demonstrate in a striking way the effect of the chain-length of the lubricant. With short-chain fatty acids, for example, the motion proceeds in 'stick-slips' and some wear takes place. When the chain reaches a certain length, smooth sliding occurs, the friction falls and the wear is appreciably reduced. With steel surfaces the transition from intermittent motion to smooth sliding occurs at a chain-length of 5 or 6 carbon atoms, that is, a molecular weight of about 100.

Film Thickness

Langmuir and Schaefer[6] were the first to show that a monolayer of a fatty acid deposited from the Langmuir trough is sufficient to reduce the friction of glass surfaces from about $\mu = 1{\cdot}0$ for clean glass to about $\mu = 0{\cdot}1$. Bowden and Leben[7], working on built-up films varying from 1 to 53 molecular layers, obtained similar results. A monolayer of stearic acid on steel produced the same low coefficient of friction as a multilayer 53 molecules thick. However, the single film was soon worn away, and for effective lubrication capable of withstanding considerable wear it was found necessary to have present a layer of lubricant several molecules thick in order to replenish the surface with fresh lubricant. These experiments also showed that even with the thickest molecular films a certain amount of wear of the metal surfaces takes place. The importance of the first monolayer has also been substantiated by other workers[6,8,9,10].

These experiments were carried out on films deposited on the metal from a surface of tap water, and they may really consist of the calcium soap rather than the fatty acid. A direct estimate of the thickness of the lubricant film may be made in another way. In some recent experiments a known quantity of 0·01 per cent lauric acid in paraffin oil was placed on a clean cadmium surface, and gave effective lubrication. The area covered by the oil was increased until the newly covered regions gave poor lubrication. From these observations it was possible to calculate the amount of lauric acid which was just sufficient to give good lubrication. It was again found that the lubricating film was of the order of 1–2 molecules thick.

With some metals, however, a monolayer of fatty acid is insufficient to provide adequate lubrication even for a single run. This falls in line with the earlier observations[1] on the friction of clean outgassed metals. In the absence of all surface films the friction was very high. With outgassed gold the admission of a trace of fatty acid vapour to the surfaces produced a decrease in friction which grew more marked with time as a thicker lubricating film formed on the surfaces. Similar results were obtained when a trace of oxygen was admitted to the surface of clean outgassed nickel, copper and gold.

It is evident, therefore, that in the lubrication of metals by fatty acids, the first adsorbed layer is, in many cases, responsible for the lubrication observed. This single layer is usually unable to provide adequate protection for the continuous traversals of the same track; for efficient lubrication in such cases an excess of fatty acid must be present to repair the damage caused by sliding. For some metals, however, a single layer is not sufficient to give adequate boundary lubrication even for the first run; a relatively thick film is necessary.

Effect of Temperature

The effect of temperature on the lubricating properties of boundary lubricants is of general interest and importance. In many parts of an engine, high temperatures may be reached in the running parts, and it is necessary to know the way in which this will affect the lubricant. For temperatures above 200° C. the main effect on a mineral oil is that of oxidation[11]. A mineral oil at room temperature will give stick-slip motion and appreciable wear. After heating for some time, the oil may develop oxidation products which will be adsorbed at the metal surface and will improve its lubricating properties; the oxidized oil will now give smooth sliding and reduce the wear. These changes are not reversible on cooling and are due to chemical changes in the oils (and sometimes the surfaces themselves). At higher temperatures after prolonged heating, gumming, corrosion and the production of other deleterious products will cause a deterioration in the lubricating properties.

A very different type of frictional change which is reversible may occur at lower temperatures[12]. For example, a typical 'high quality' commercial lubricant on a steel surface will give smooth sliding and slight wear. On warming the steel surface to 70° C., the motion changes from continuous sliding to stick-slips; on raising the temperature further, the stick-slips increase in size, the friction rises and a corresponding increase in wear takes place. Provided the heating has not been sufficient to cause appreciable oxidation of the lubricant, these changes are completely reversible on cooling. This effect has been investigated for pure substances[7]. For pure paraffins and straight-chain alcohols the transition occurs at the bulk melting point of the compound. For the substances the transition temperature is sharp a clearly defined.

With fatty acids the transition temperature depends upon the load, speed and the experimen conditions, but it is considerably *higher* than the bu melting point of the fatty acid. Under the conditio of measurement used by Frewing and Tabor, T f fatty acids on steel was about 70° C. above the bu melting point. Under the different experimen conditions which obtained in Hughes and Whittin ham's experiments[8], T was about 30° C. higher th the melting point. These workers also showed th the frictional properties and transition temperatu of fatty acids deposited as a monolayer, or as monolayer covered with paraffin oil, or as acid bulk, are essentially the same. These results aga show that the first monolayer is responsible for t lubricating properties of the lubricant and for t phenomenon associated with the measurements of

Nature of the Underlying Surfaces

Little work of a consistent nature has been carri out on the effect of the underlying metal on th lubricating properties of given lubricants. Har made some comparative measurements of the c efficient of static friction μ_s on steel, glass ar bismuth surfaces and found that for any give hydrocarbon, fatty acid or alcohol, μ_s for glass is le than μ_s for steel, which is less than μ_s for bismut Sameshima carried out some similar experiments o steel, glass and silver surfaces. He found that gla was poorly lubricated, whereas steel was well lubr cated, by fatty acids and alcohols. Silver showed a intermediate behaviour.

A more systematic investigation has been describe by Hughes and Whittingham[8], who compared th lubricating properties of stearic acid and a com mercial oil on various metal surfaces. They showe that for the commercial oil the value of T was ver dependent on the nature of the metal substrate. Fo stearic acid, however, they found that both μ and were not greatly dependent on the nature of th substrate whether it was of silver, lead, tin, alum inium, cast iron, stainless steel, copper or even coppe oxide or copper sulphide. In these experiments however, they used an upper slider of a fixed meta throughout (steel). This clearly introduced an un certainty into the interpretation of the results.

A series of experiments has recently been carrie out using similar metals for both the upper and th lower surfaces. The lower surface was a flat plat and the slider was hemispherical. Comparativel heavy loads of approximately 4,000 gm. were use and the sliding speeds were slow, c. 0·01 cm./sec The results show that the lubricating properties o the fatty acids depend very markedly upon th nature of the metal. One of the most striking result is that, for unreactive surfaces such as nickel platinum, silver and glass, fatty acids are scarcely more effective as lubricants than saturated hydro carbons. These results led to some measurements o the chemical reactivity of the various surfaces wit fatty acids under standard conditions. Lauric ac was used and the metal surface heated up to 150° C. with the acid in contact with it. The results at once showed that the metals fall into two distinct classes: (*a*) in which chemical attack is absent or is barely detectable; and (*b*) those for which chemical attack is marked (see table).

FICIENCY OF LUBRICATION WITH 1 PER CENT LAURIC ACID IN PARAFFIN COMPARED WITH REACTIVITY OF THE METAL TO LAURIC ACID.

Metal	Coefficient of friction (20° C.)	Transition temperature (° C.)	% Acid* reacting	Type of sliding at 20° C.
Zinc	0·04	94	10·0	Smooth
Cadmium	0 05	103	9·3	"
Copper	0 10	97	4·6	"
Magnesium	0·10	80	Trace	"
Iron	0·15–0 20	*c.* 40–50	"	Irregular (smooth)
Platinum	0·25	20	0·0	Stick-slip
Nickel	0·28	20	0·0	"
Aluminium	0 30	20	0·0	"
Chromium	0·34	20	Trace	"
Glass	0·3–0·4	20	0·0	Stick-slip (irregular)
Silver	0·55	20	0·0	Stick-slip (large)

* Estimated amount of acid involved in the reaction assuming mation of a normal salt.

As silver, copper and platinum are the only metals at are electropositive to hydrogen, the absence of action in the other metals must be due to the esence of a relatively stable oxide film. This is pported by some observations on aluminium. If e surface layer was scraped off so that the freshly xposed metal came in contact with the fatty acid, fective lubrication occurred. Where reaction occurs is probable that it occurs mainly in two stages:) the atmospheric oxidation of the metal, (2) re-ction of oxide with the acid. This has been con-rmed by Dubrisay[13] in his experiments on the orrosion of metals by solutions of fatty acids in ydrocarbons. It is apparent, therefore, that the ajor factor in determining the reactivity is not the osition of the metal in the electrochemical series ut the reactivity of the oxide film and its rate of eformation.

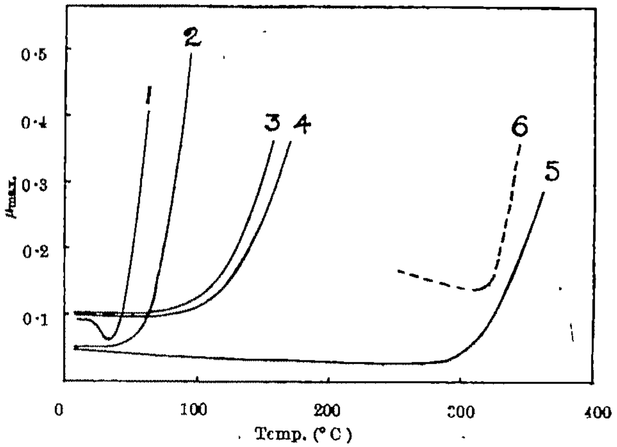
It is not suggested that there is a simple quantita-ive correlation between the coefficient of friction nd the reactivity of the surfaces, but it is clear that hose metals which are most effectively lubricated re also those which are most readily attacked hemically by the fatty acid. On the other hand, the unreactive metals and glass are poorly lubricated and give stick-slip motion with relatively high coefficient of friction. Further experiments showed that the less reactive metals, such as iron and aluminium, require a high concentration of lauric acid for the best lubrication. The unreactive metals, however, are not lubricated well even by pure acids unless the acids are solid. The lubrication of chromium and silver is of some practical importance at the present time, and it is interesting to note that neither of these is effectively lubricated by fatty acids.

Lubricating Properties of Metal Soaps

These results show that, under these conditions of sliding, the fatty acids themselves are only effective as lubricants when they react with the surfaces concerned. That is to say, lubrication is effected, not by the fatty acid itself, but by the metallic soap formed as a result of chemical reaction between the metal and the fatty acid. (It is interesting to note that an ester such as ethyl stearate does not lubricate above its bulk melting point on copper and cadmium surfaces. The behaviour on steel, however, appears to be anomalous and is the subject of a further investigation.) This view has been confirmed by several experiments on the lubricating properties of metal soaps. For example, a solution of copper laurate in paraffin oil gives the same frictional properties and transition temperature on copper as a dilute solution of lauric acid in paraffin oil. Further, the transition temperature (about 100° C.) is close to the temperature at which copper laurate begins to soften[14]. In this connexion it is interesting to recall the electron diffraction experiments of Tanaka[15], who found that stearic acid (m.p. 69° C.) on copper loses its high degree of lateral orientation between 120° and 130° C. Similar results for stearic acid on steel have been observed by Beeck, Givens and Smith[16]. More recently, Mr. A. Cowley has carried out some similar (unpublished) experiments with palmitic acid. He finds that a monolayer of palmitic acid (m.p. 62° C.) on cadmium loses its characteristic orientation at about 110° C. Monolayers of cadmium palmitate show exactly the same behaviour on both cadmium and platinum substrates. The softening temperature of cadmium palmitate is approximately 110° C. and frictional measurements show a breakdown at about the same temperature.

Similar behaviour is observed in the lubrication of platinum surfaces by metal soaps. Pure lauric acid, or lauric acid in paraffin, will not lubricate platinum at temperatures above 43° C., which is the melting point of the acid. If copper laurate is deposited from an ethereal solution on a platinum surface, the surface is lubricated up to temperatures of about 100° C., that is, the transition occurs at approximately the same temperature as that observed with lauric acid on copper. If, however, a solution of copper laurate in paraffin is applied to a platinum surface, the breakdown occurs at a much lower temperature and this must be attributed to the increased solubility of the metal soap in the paraffin. It is apparent that the breakdown of the lubricant film may be due either to a direct loss of rigidity by thermal softening or to a dissolution into the superincumbent liquid.

The importance of the physical properties and texture of the lubricating film is shown by experiments on sodium stearate applied to steel surfaces. If the soap is applied as a wet smear, breakdown occurs around 100° C. and is attributable to the ebullition of the excess water which disrupts the lubricating layer. If, however, the soap is applied



EFFECT OF TEMPERATURE ON FRICTION.

1. Solid docosane (m.p. 43° C.) on platinum surfaces. 2. Solid stearic acid (m.p. 69° C.) on platinum surfaces. 3. Solid copper laurate (softening point 110° C.) on platinum surfaces. 4. 1 per cent lauric acid in paraffin oil on copper surfaces. 5. 'Dry' film of sodium stearate (softening point 290° C.) on steel surfaces. 6. Thin film of lead (m.p. 327° C.) on hard steel surfaces.

from an ethereal solution, it retains its lubricating properties up to 300° C., which corresponds to the temperature at which sodium stearate softens and becomes a mobile liquid[14]. The behaviour of long-chain fatty acids on unreactive surfaces is thus similar to that of long-chain hydrocarbons, and to that of thin films of soft metals deposited on hard substrates which lubricate until the melting point of the film is reached. This behaviour again is similar to that of metallic soaps which, as pointed out above, maintain their lubricating properties until the temperature reaches the softening point of the soap. These similarities are shown in the accompanying graph, where it is seen that docosane (m.p. 44° C.) and stearic acid (m.p. 69° C.) lubricate platinum surfaces until they melt; a thin film of lead (m.p. 327° C.) lubricates steel until the melting point of the lead film is reached; sodium stearate lubricates steel until the stearate softens and melts (about 300° C.). Finally, lauric acid in paraffin lubricates copper until the softening point of copper laurate is reached (about 100° C.).

Mechanism of Boundary Lubrication

All our experiments have shown that even with the best boundary lubricants and comparatively light loads, there is some wear and damage of the metal surfaces. The underlying metal is, in fact, torn to a depth which is large compared with the dimensions of a molecule. A large part of the surface may show little sign of damage but, at various localized points of contact, there are definite signs of metallic adhesion through the lubricant film and minute fragments of one metal may be left welded on to the other[17,18,19]. This means that the friction of lubricated metals cannot, in general, be due simply to the sliding of one monolayer over the other; nor, indeed, can it be merely a function of the surface forces as Hardy supposed. It must be greatly influenced by the bulk properties of the metals concerned.

It has been shown that for unlubricated metals the frictional resistance F can be conveniently written

$$F = S + P,$$

where S is the force required to shear the metallic junctions formed at the points of contact and P is a ploughing term. Under some conditions the ploughing term may be small, and if this is neglected,

$$F = S = As,$$

where A is the real area of contact between the metals and s is the shear strength of the junctions. With clean metals the welding is strong, so that the break frequently occurs within the metal itself. In this case s will be equal to the shear strength of the metal. An effective lubricant will diminish the area of metallic contact although, as we have seen, it is rarely able to prevent it altogether.

When lubricated metal surfaces are placed in contact, plastic flow of the metals occurs until the area is large enough to support the applied load. The pressure, however, will not be uniform over the whole region of contact. At some points it will be very much higher, and at these points a local breakdown of the lubricant film may occur. The extent of the breakdown will naturally depend on the nature of the lubricant film. Further, if the sliding speeds are appreciable, it will be aided by local high temperatures developed during sliding. As a result of the partial breakdown of the lubricant film, metallic junctions, large compared with the size of a molecu are formed between the surfaces. The resistance motion is then due largely to the force necessary break these junctions. There will also be so resistance to sliding by the lubricant film itself, a we may write

$$F = A(\alpha s_m + (1-\alpha)s),$$

where A is the area which supports the applied loa α is the fraction of this area over which breakdow of the film has occurred, s_m is the shear strength the junctions at the metal-metal contact, and s the shear strength of the lubricating film. Wi a good lubricant the area over which metallic co tact occurs may be very small indeed. Neverthele the shear strength of these junctions may be so hig compared with that of the lubricant that they ma be responsible for the greater part of the resistan to motion.

The main purpose of the lubricant film is, ther fore, to reduce the amount of metallic conta between the surfaces by interposing a layer that not easily penetrated and that possesses a relativel low shear strength. In order to prevent appreciab contact, the lubricating layer must, in addition t being firmly attached to the surface, possess a stron lateral adhesion between the hydrocarbon chains. I the film softens or melts, that is, if the lateral adhesio between the chains falls to a low value, metalli seizure occurs with a corresponding increase i friction and wear. The fact that *solid* films o saturated hydrocarbons are more effective in lubri cating unreactive metals than fatty acids above thei melting point shows that the strength of the latera adhesion between the large hydrocarbon molecules i at least as important as the strength of attachmen to the surface.

As we have seen, at the loads used in our experi ments, fatty acids in themselves are scarcely mor effective as boundary lubricants when applied to unreactive surfaces than saturated hydrocarbons. Even when they form well-adsorbed and orientated films on platinum or nickel surfaces, they do not lubricate above their bulk melting points. This means that even the longest-chain fatty acids do not lubricate unreactive surfaces at temperatures above about 90° C. The softening points of metallic soaps, however, are usually very much higher than the melting points of the pure acids. For this reason fatty acids are much more effective as boundary lubricants at heavy loads and high temperatures if they are used in the form of metallic soaps. This may be achieved by applying them to metal surfaces with which they react. The metal soap is then formed *in situ* and is well attached to the surface. In many cases even a monolayer of such a film is sufficient to prevent much penetration and metallic contact; in other cases, however, appreciably thicker films may be necessary. These films maintain their lubricating properties with increasing temperature until the softening point of the soap is reached. At this stage the film softens or melts, and increased metallic contact occurs through it, with corresponding increase in friction and wear. As the soap film loses its lateral adhesion, its linkage to the metal surface also grows weaker, and the breakdown of the lubricant film is often accompanied by its dissolution into the superincumbent oil or excess acid.

If the metal surface is unreactive, the fatty acid will not lubricate above its bulk melting point, and st be applied as a metallic soap. In such cases e physical texture and the mode of deposition of ese films may be very important. The best fric- nal properties are obtained when the soap film has lose coherent texture, is evenly deposited over the rface and is well adsorbed. These films will lubricate til the softening point of the soap occurs. If, how- er, the adsorption of the soap to the surface is ak and there is a superincumbent layer of oil esent, it may dissolve in the excess oil at a tem- rature lower than its softening point. If there are lvents present in appreciable quantities in the soap m, violent ebullition may cause them to disrupt e lubricant film. In both cases breakdown of the bricant film will tend to occur at temperatures low the softening point of the metallic soap.

The softening point of a soap is not clearly defined and ay cover a wide temperature range. The actual tem- erature at which the weakening of the soap film is fficient to cause an appreciable increase in metallic izure (and hence in the friction and wear) will early depend on the physical conditions of the xperiment. With hard surfaces, where the pressures e high, or with extremely slow surface speeds, we ould expect the breakdown to be discernible at wer temperatures. This is generally found to be e case—with any given metal and lubricant the ansition temperature T is dependent in this way pon the load, speed and shape of the sliding surfaces. t higher sliding speeds the formation of a viscous oap film of appreciable thickness may lead to a ydrodynamic separation of the surfaces. The condi- ions are no longer those of true boundary lubrication nd the friction may fall to a very low value (see the nteresting paper by Beeck, Givens and Smith[16] on quasi-hydrodynamic lubrication). The frictional behaviour of these soap films resembles in many respects the lubricating properties of thin films of soft metals deposited on hard substrates. This similarity has already been discussed in earlier papers. One of the most marked differences, however, is that even on rough surfaces a single molecular layer of soap may provide effective boundary lubrication, whereas metal films must be appreciably thicker (c. 10^{-6} cm.). The very high tenacity of the soap monolayer and its ability to prevent metallic seizure is, indeed, remarkable.

This view of the role of the lubricating film has been supported by recent work on the action of extreme-pressure lubricants and has led to the development of lubricants which maintain their boundary lubricating properties at very high temperatures.

BIOCHEMICAL ASPECTS OF MENTAL DISORDER

SOME aspects of the biochemistry of mental disorder were discussed at a meeting of the Psychiatry Section of the Royal Society of Medicine on May 24.

Recent biochemical investigations into mental disorder were surveyed by Dr. G. D. Greville, who opened the proceedings. He dealt in the first place with the excretion of hippuric acid by schizophrenic patients after sodium benzoate administration. Quastel and Wales found, in a routine examination of schizophrenic patients, that a group of eighteen catatonic patients showed without exception impaired rates of hippuric acid excretion. In a group of twenty-seven non-catatonic schizophrenics, all but four gave hippuric acid excretions of the normal value and normal range of variation. Since none of the cases chosen for examination showed signs of renal or hepatic impairment, Quastel and Wales suggested that a metabolic disturbance in the liver might be a characteristic feature of catatonic patients. Strom-Olsen, Greville and Lennon repeated this work with sixty-two schizophrenic patients of whom twenty-eight were considered to be catatonic. They found that only five of the catatonic patients gave abnormally low values of hippuric acid excretion, the proportion being about the same as among non-catatonic schizophrenic patients. Such a finding seemed not to indicate any noteworthy difference between catatonic and other schizophrenic patients so far as benzoate detoxication is concerned. There was agreement, however, that a small but not insignificant proportion (18 per cent) of non-catatonic schizophrenic patients without obvious renal or hepatic disturbance give abnormally low rates of excretion of hippuric acid under the standard test conditions.

Quastel and Wales then repeated their work using an intravenous method of benzoate administration to avoid a possible complication due to faulty absorption of benzoate from the gut and confirmed their original findings. Moreover, they obtained evidence that the clinical condition of the patient at the time of the test may have an important bearing on the rate of benzoic acid detoxication, for certain patients who had previously shown low rates of hippuric acid excretion exhibited normal rates after improvements in their mental condition due to treatment. Subsequent workers (Davies and Hughes; Finkelman *et al.*) have confirmed that abnormally low rates of hippuric acid excretion may occur in a large proportion of catatonic cases, but others (Gildea; Michael, Looney and Borkhovic) could obtain no evidence for such low excretions. Dr. Greville showed that the discrepancy between the results of the various workers could not be due to a failure to take into account the body-weight of the patients. Muscular rigidity may be a factor associated with the lowered rate of excretion according to Finkelman, but no satisfactory explanation is as yet forthcoming to account for the different sets of results.

Dr. Greville then turned to a consideration of the spontaneous hypoglycæmia which sometimes develops in the psychoneuroses and other abnormal mental conditions, and commented upon the development of emotional disturbances, often leading to behaviour of an anti-social character, during the periods of hypoglycæmia. Hypoglycæmia frequently occurs in children whose ill-behaviour in this condition can often be improved by giving them sweets. He dealt with some of the work on carbohydrate metabolism which has been carried out on psychotic patients by means of glucose tolerance tests, measurements being made in these tests of the rates of appearance and subsequent disappearance of blood-sugar after oral ingestion of glucose. McCowan and Quastel showed that among manic-depressive patients, those exhibiting a high emotional tension gave a high hyperglycæmic index, a term coined by these workers to give a quantitative expression to the divergence between an abnormal and a normal oral-glucose tolerance curve. The patients on recovery showed a low or zero index, the value found in normal mental conditions where there is no complication due to physical factors affecting glucose metabolism in the body.

Gildea and his colleagues, as a result of their work on oral and intravenous-glucose tolerance curves in manic depressive patients, concluded that abnormal oral-glucose tolerance curves leading to a high hyperglycæmic index are largely due to delayed absorption of glucose from the gut. This conclusion is supported by the observation by Davis and Greville that in depressed patients there exists a correlation between the slope of the initial portion of the glucose tolerance curve and the hyperglycæmic index. The lower the initial rate of rise of blood-sugar, the more sustained is the hyperglycæmia. It seems probable that with a constant carbohydrate intake the factor which largely determines the initial stage of a sugar tolerance curve is the rate of absorption of the sugar from the alimentary tract. It thus appears evident that there is a correlation between this rate and the emotional state of the patient.

Dr. Greville finally mentioned recent work (for example, that of Gibbs) on the oxygen consumption of the brain as measured by differences between arterial and venous contents of oxygen, and by the rate of blood flow to the brain. It seems to be clear from the work of Wortis that there is no measurable difference between the rates of oxygen consumption of the brains of normal and schizophrenic individuals. Himwich and Fazekas conclude that cerebral oxygen uptake is normal in a group of undifferentiated mental defectives, but that it is probably reduced in mongolism, cretinism, phenylketonuria, and microcephaly. Little is known as yet of the changes occurring in the brain during the shock therapies commonly used in the treatment of schizophrenia, but there is evidence that marked changes of metabolism do take place. This is clear, for example, in insulin shock treatment, where a large reduction in the arterio-venous difference of oxygen content takes place, while the rate of blood flow is unaffected. It is unreasonable to expect that the cerebral metabolic changes will be identical in all forms of shock therapy, which differ so much in intensity and duration and which are by no means all equally effective.

The biochemical aspects of anxiety were discussed by Dr. D. Richter. He pointed out that the blood of patients with anxiety contains a substance which is absent from normal blood and which exerts a specific action on plain muscle. It has also been shown by Gellhorn and his colleagues that in emotional excitement there is a release of insulin into the blood. This is an effect which can be measured quantitatively, and should help in elucidating the details of the close association betwe anxiety states and the endocrine balance.

An emotional hyperglycæmia has been frequent reported, but many investigators have failed confirm this. Dr. Richter has carried out blood-sug estimations on patients with anxiety states and normal subjects during air raids at the Neuros Centre at Mill Hill. About one third of the subjec showed a slight rise in blood-sugar level when expose to immediate danger, but the rise was never ve great. He referred to further work at Mill Hill whic showed that serum choline esterase activity increased in anxiety states and in depression. rise can also be produced in normal subjects b vigorous exercise or by exposure to low temperature The effect is attributed to an increased autonom activity and is apparently specific for cholin esterase.

Dr. Richter observed that during the last fe years there has been a tendency to depart from th point of view concerning anxiety states held b Cannon and his associates. In acute emotional state there is a general lability of autonomic control which many apparently unrelated biochemical factor may be involved. The pattern of responses, instea of being uniform, shows considerable variations i different individuals, and there is little evidence tha they serve any useful biological purpose. A variet of biochemical factors may play a part in the onse of anxiety states, as for example, hypoglycæmia aneurin deficiency or adrenaline release. Anxiet may be a symptom of almost any physical disability to which the individual is unable to adjust. Recent work on patients with 'effort syndrome' has shown how a biochemical lesion causing an impairment of physical efficiency can lead to the onset of an anxiety neurosis.

The discussion was opened by Dr. J. H. Quastel, who commented upon the diversity of results obtained by different workers on the rates of hippuric acid excretion in catatonic patients submitted to a standard test. He emphasized the dependence of these rates on the clinical conditions of the patients, and urged the great importance of close association and co-operation between the psychiatrist and the biochemist in correlating the results of a biochemical test with the patient's mental and physical condition at the time of the test. The lack of agreement between the results of metabolic investigations in the field of schizophrenia may be largely due to the fact that such a field is far from homogeneous and the individual schizophrenic patient shows much variation in mental state and physical condition over a period of time. For progress in such work it is essential to select a small field where there is some approach to homogeneity and to examine cases in such a field periodically. The interesting results of Gjessing on the metabolic changes associated with changes in the mental state are probably due largely to his selection and continuous examination of a small number of schizophrenics conforming to a special group of periodic catatonia which is characterized by repeated attacks of stupor and excitement. Gjessing concludes that the mental disturbance follows directly upon a disturbance of nitrogen metabolism, and suggests that at the time of change of phase a toxic substance is produced which is connected with the disturbance of protein metabolism and which acts in an inhibitive or irritant manner on the central nervous system.

Although there is no convincing evidence, in Dr.

stel's opinion, that impaired oxidations in the in play an important part in schizophrenia, the itivity of the cortex to anoxia is such that lized changes may result in abnormal mental ifestations with but little overall change in the n metabolism. It is important to take into conration not only the availability of oxygen or of ose (the main fuel of the brain) to the nerve cell also that of a variety of other factors, all indissable for the normal rate of oxidation of glucose the cell. Among such factors are nicotinamide, urin, riboflavin and adenylpyrophosphate. If re is a local deficiency of these substances, or some erference with their activities, the results, so far the nerve cell is concerned, may be as far-reaching their consequences as the deprivation of the oxygen of the glucose supply. The sensitivity of the cortical ue to anoxia may be a factor concerned with the eficial effects of shock therapy, but too little is own as yet of the effects of these treatments on metabolism of the central nervous system to come any definite conclusion.

Referring to the work on glucose tolerance tests d emotional states, it was pointed out that Lockwood s observed a dependence of the hyperglycæmic lex on the affective state as indicated by the ychogalvanometer.

Interesting results are now being obtained with e use of the electro-encephalogram on the conxion between biochemical activities of the brain d its electro-physiological properties. Studies such these should help to throw light on the manner in hich biochemical and electrophysiological phenmena connected with the central nervous system are nked with the mental state.

Dr. R. Benesch referred to work carried out by im in collaboration with Dr. P. Ellinger on certain icotinamide-deficiency syndromes, namely, pellagra nd the acute psychoses of the Cleckley-Sydenstricker ype. Ingestion of nicotinamide normally leads to he excretion of nicotinamide methochloride. Benesch nd Ellinger have shown that large differences in the asal output of nicotinamide methochloride, and in he output after nicotinamide administration, exist etween control subjects and pellagrins as well as acute psychoses with a suspected nicotinamide eficiency. The mental confusion present in such ases clears up after nicotinamide treatment. They urther showed that human intestinal flora are capable of synthesizing nicotinamide, so that a diet may inhibit the development of pellagra quite independently of its content of nicotinic acid. Thus the nature of a diet and the type of bacterial flora it encourages in the human intestinal tract are important factors to consider in the development or treatment of nicotinamide-deficiency disorders.

In general discussion it was pointed out that choline esterase is exceptional in presenting an example of an enzyme passing into the blood concomitantly with the development of an anxiety state or of an increased autonomic activity. Its appearance in the blood, however, will not, according to Dr. Richter, invalidate its use as a test for liver function. Further discussion ranged around the association of incipient pellagra with porphinuria and the fact that sulphonal poisoning may produce pellagra-like symptoms.

It was suggested by Dr. Mackenzie that a patient might most profitably be presented for biochemical investigation at a time corresponding to a definite phase of his behaviour, rather than on the basis of his psychiatric classification.

OBITUARIES

Sir Peter Chalmers Mitchell, F.R.S.

PETER CHALMERS MITCHELL was born at Dunfermline on November 23, 1864, and died in London, as the result of an accident, on July 2, 1945. He was the eldest son of the Rev. Alexander Mitchell, and was educated at Aberdeen Grammar School, the University of Aberdeen, and at Christ Church, Oxford, where he was an exhibitioner. He also studied in Berlin and Leipzig. He became senior University demonstrator in comparative anatomy and assistant to the Linacre professor at Oxford in 1888, and during 1891–93 was organizing secretary for technical instruction to the Oxfordshire County Council. Afterwards he went to London as lecturer in biology at Charing Cross Hospital and at the London Hospital. During this period he carried out various comparative studies mainly on the anatomy of birds, and in the course of this work spent much time at the prosectorium of the Zoological Society. About this time he published his "Outlines of Biology" and "Thomas Henry Huxley: A Sketch of his Life and Work", an outstanding biography which perhaps more than any other of his writings reveals his literary gifts. He also translated Metchnikoff's "The Prolongation of Life, Optimistic Studies" and O. Hertwig's "The Biological Problem of To-day. Preformation or Epigenesis ?".

Mitchell will be remembered mainly, however, for his very great services as secretary of the Zoological Society of London from 1903 until 1935. During this period, by a judicious blending of popular and scientific interests, it became the leading zoological society in the world, a great popular and scientific institution, and a model for the many similar societies which sprung up during the twentieth century. Some idea of its progress may be gathered by the fact that between 1903 and 1935 the number of fellows increased from approximately 3,500 to more than 8,000, and the annual number of visitors to the Gardens from approximately 690,000 to more than 2,000,000. During his term of office the Zoo was largely rebuilt, the most notable additions being the Mappin Terraces, Aquarium, Reptile House, Monkey House and Monkey Hill. In addition, he was entirely responsible for the creation of Whipsnade Zoological Park, a monument to his energy, imagination and organizing ability. He himself regarded Whipsnade as his crowning achievement on behalf of the Zoological Society, and there he made his country home after leaving Malaga. His "Centenary History of the Zoological Society of London", published in 1929, contains an excellent account of the growth of the Society and the development of its various activities, including both Regent's Park and Whipsnade.

Apart from his zoological interests, Mitchell devoted much of his time to journalism and for many years was scientific correspondent of *The Times*, a regular leader writer, and that journal's adviser upon scientific matters. He was also chairman of the council of management of the "World List of Scientific Periodicals" from its beginning until 1935, and remained an active member of that organization until his death. He was largely responsible for the preparation of the volume which, in its second edition (1934), gives the titles and standard abbreviations of more than 36,000 periodicals.

After his retirement, Mitchell went to live at Malaga, but in 1937 political events debarred him from remaining there and he returned to London, when he published "My Fill of Days", a record of his long and interesting life, and in the next year "My House in Malaga". For the last three years he had been honorary treasurer of the Joint Committee for Soviet Aid, which raised considerable sums of money for providing supplies for the U.S.S.R.

Mitchell had a most attractive personality, and with his keen though somewhat sardonic humour was a very persuasive talker. He had a great natural fondness for animals and was for many years president of the Universities Federation for Animal Welfare. He took an active interest in the protection of wild life generally, and was an active member of the Society for the Preservation of the Fauna of the Empire, being president during 1923–26 and afterwards a vice-president until his death.

He was elected to the Royal Society in 1906; in addition, he received numerous academic and public awards, and was knighted in 1929.

EDWARD HINDLE.

Brigadier-General Sir Percy Sykes

BRIGADIER-GENERAL SIR PERCY SYKES, who died on June 11, was an authority on Persia on account of the many years he lived there, his historical writings, and his numerous journeys through it. He also made exacting expeditions in Central Asia. He travelled with a historian's bias which served to people desolate roads and to link dreary adobe ruins or scattered shards of pottery with happier and perhaps splendid days in the past. During much of his travelling life he had the advantage of official status and prestige, but this was less important than the courage and audaciousness with which he flouted the dangers of travels fifty years ago, and the tough body and sturdy health which enabled him to endure hardships of the road and stays in infected Persian towns. No tales of insecurity would deflect him from his purpose, nor would the very real risk of a clash with slave raiders deter him from following a route chosen because it was little known or infrequently used.

Sir Percy's most important journeys were in Eastern Persia, north, central and south. Fifty-two years ago he followed the River Atrek from the shores of the Caspian into the gorges near Bujnurd. This meant crossing the marches between the unruly Turkomans and the Kurdish settlers put there to hold them at bay, and this he did adventurously alone. Many years later he filled in details along this little-known valley, from the prosperous populous headwaters near Kuchan to the uninhabited wastes near the Russian border. On his first journey he also crossed the Lut from Meshed to Kerman. During the next twenty years he filled posts at both these cities, and as he never liked to follow the same road twice he was able to amplify the traverses he made in a regional way.

Farther south Sir Percy crossed Persian Baluchistan on intersecting trails and climbed Taftan, Bazman and Hamant, all of them high enough to provide comprehensive views over hundreds of square miles of unexplored territory. Two of these mountains are young volcanoes standing more than two hundred miles from the sea, and their discovery did something to discourage the fallacy that volcanoes are only to be found close to the sea and to depend upon the breaking in of sea water to the depths of the earth's crust for their activity. He was responsible for m new facts regarding the Jaz Murian basin, an probably the only European who has penetrated valley of Ramishk. He had an opportunity of visi the wind-stricken Seistan depression, where Afghan Helmand discharges, and on the way ad to the knowledge of the eastern rim of Persia w extends four hundred miles south of Meshed Birjand. As commander of the South Persian R during the War of 1917–18, he had further op tunities for travel and the services of surveyors extended his mapping.

Apart from the geographical aspect of his w Sir Percy made noteworthy archæological discove in Eastern Persia and studied the manners customs of the people.

J. V. HARRISO

SIR PERCY SYKES was a true embodiment of tradition which makes a British officer posted in East take interest in every aspect of Nature and around him. His geographical exploration m exceeded the utilitarian purposes of his official dut His earliest and most original work, "Ten Thous Miles in Persia, or Eight Years in Persia" (19 was very favourably received both in Great Brit and abroad. It contains a great mass of fr observations on the antiquities, history and ethnolo of eastern Persia. The work was continued in a ser of reports on the journeys in Khorasan, etc., writ in the same vein and published in the *Geographi Journal*. Small notices on the Gypsies, the Pa and prehistoric remains, which he contributed to su organs as the *Journal of the Royal Anthropologi Institute, Journal of the Royal Society of Arts*, et were also interesting, and often started further use discussion among the specialists.

Sir Percy was no professional Orientalist bu working with the help of his *munshis*, he easily fou in the original sources references to illustrate h descriptions. This is particularly noticeable in h notes on the famous mosques of Meshed. Man curious details on the pilgrimage to this sanctuar are recorded in the memoir prepared by one of h Muslim assistants and published in his translatio under the title "The Glory of the Shia World" (1910

Sir Percy's main interest lay in Persia, and h second book of travel, "Through Deserts and Oase of Central Asia" (1910), written in collaboration wit his sister, the late Miss Ella Sykes, had a much mor popular form. It summed up the impressions of hi journey through Russia in 1915, of his temporar term of office as Consul General in Kashghar and o his hunting expeditions in the Pamir.

More ambitious were his historical works. Hi two volume "History of Persia" went through thre editions (1915, 1921 and 1930) and has been recentl translated into Persian. For the earlier periods Si Percy naturally depended on the contributions o his collaborators, but from A.D. 1600 on the book contains many interesting items on the relation of Persia with Europe and particularly with Grea Britain. In the additions to the third impression, the author recorded his personal experiences in Fars during the disturbances which followed the first European War.

The biography of Sir Percy's former chief, the Right Hon. Sir Mortimer Durand (published in 1926), formed a transition to a new field of his studies: in 1940 appeared his two-volume "History of Afghanistan". The book is a useful summary of the great mass of information found in English publications, and partly in official archives.

In the interval between the two "Afghanistan" books appeared "A History of Exploration from the Earliest Times to the Present Day" (1934). The volume covers a vast field and is particularly helpful in the chapters on Central Asia, the area on which the author ever kept a watchful eye. As a supplement to it came "The Quest for Cathay" (1936), popularizing the data of the Hakluyt series.

If to this enumeration of the principal works we add a number of occasional articles in the *Royal Central Asian Journal*, etc., and prefaces to the joint-effort books and translations, we shall recognize how well Sir Percy employed the leisure hours of his busy official life and the years of his retirement. His contribution to the knowledge of the Middle East and its manifold problems has been considerable and conspicuous.

V. Minorsky.

Prof. L. I. Mandelstam

Prof. L. I. Mandelstam, an outstanding Russian physicist and member of the Academy of Sciences of the U.S.S.R., died in Moscow on November 27, 1944, when at the height of his powers. Mandelstam was endowed with an unusually profound and subtle mind. He was at once a brilliant experimenter, an outstanding theoretical worker, a profound thinker, especially interested in the problems of epistemology and of the philosophy of science, and an outstanding expert in radio-engineering.

Mandelstam was born in 1879 in the south of Russia. He was educated at the University of Strassburg, where he began his scientific career as Prof. F. Braun's assistant; he became a *Privatdozent* in 1907 and obtained the title of professor in 1913. Together with N. D. Papalexi, his life-long collaborator, he carried out in that period a number of physical and technical researches of importance to the new subject of radio-engineering. He was the first to demonstrate the advantages of weak coupling (1904), which has since received wide practical application; he developed the method of the excitation of aerials with a prescribed phase difference (1906), and originated other technical advances.

Mandelstam's characteristic ability to discover deep inner ties between apparently unconnected phenomena soon directed his attention to another branch of physics, namely, optics, and particularly to the problem of the scattering of light, which throughout his life remained of prime interest to him. Mandelstam was the first to demonstrate, in 1907, that the lack of optical homogeneity of the medium is the necessary condition for the molecular scattering of light which is due to radiation of atomic oscillators vibrating with definite phase relationships. This fundamental conclusion cleared the way for establishing the fluctuating nature of scatter; Mandelstam himself followed up this work with a statistical theory of scattering of light on the surface of a liquid (1913). A number of other beautiful researches in optics were carried out during this period.

In 1914, Mandelstam returned to Russia, and his most creative period was the last twenty years of his life, after his election to a professorship in the University of Moscow in 1925 and to the membership of the Academy of Sciences in 1929. Mandelstam's lectures at Moscow were unsurpassed examples of university teaching, in which the borderline between teaching and creative scientific research vanished; not infrequently, during these lectures, problems originated that became later the subjects of scientific investigations.

Mandelstam's researches in the physics of oscillations were now given a new impetus. A master of the classical theory of oscillations, Mandelstam was clearly aware of its limitations and realized the necessity for developing a new 'non-linear' system of ideas and methods, that would be adequate to the new problems suggested particularly by the development of radio-engineering. He and his pupils searched persistently for these new methods, developing a theory of non-linear oscillations which gave fundamental results in the most varied branches of physics: radio, hydrodynamics, aerodynamics, the theory of automatic regulation and others. Mandelstam himself carried out a number of these important researches in collaboration with Papalexi, as for example the discovery of the phenomenon of resonance of the *n*-th kind, the so-called parametric filter based on this phenomenon, an important generalization of the conception of resonance, and the development of a new type of a generator of alternating current (the so-called parametrical machine).

Proceeding from optical analogies, Mandelstam and Papalexi invented radio interference devices, in particular the radio range-finder, by means of which precision measurements of the velocity of propagation of radio waves in varied conditions were carried out, and a new sphere of radio application developed, namely, radio-geodesy, which is now made use of in the Soviet Arctic regions as well as other parts of the U.S.S.R.

During the same period, Mandelstam and his collaborators carried out important optical investigations. Introducing into optics the conception of the modulation of oscillations, Mandelstam in 1918 came to the conclusion that the scattering of light must be accompanied by a change of frequency, conditioning the fine structure of scattered light. Experimental search for this phenomena led Mandelstam and Landsberg to the fundamental discovery of combinational scattering of light in crystals. Their first publication was dated May 6, 1928, and soon it became clear that the phenomenon discovered by them was of the same nature as the combinational scattering of light in fluids, simultaneously discovered by Raman, announced on March 31 of the same year, and since known as the Raman effect.

In the course of many further researches on the scattering of light, Mandelstam's attention was attracted to the absorption of ultra-acoustic waves. A relaxation theory of this phenomenon, developed by him in 1936, gave rise to a series of experimental researches in this direction.

Of late, Mandelstam's scientific interests turned primarily to the fundamental problems of quantum mechanics. He was the first to deduce the uncertainty relation between time and energy from the general formalism of quantum mechanics, and to reveal the simple physical meaning of this fundamental relation. In a course of his lectures on the theory of measurements of quantum systems, Mandelstam gave an interpretation of the theory unsurpassed in its clarity and depth; in particular, he pointed out the fundamental distinction between direct and indirect measurements of quantum systems, which is of great importance to the further development of quantum theory.

Mandelstam's published works do not do justice to his many-sided scientific interests. He was generous in imparting his ideas to friends and collaborators, so that much which was really his appeared under another's name. Also, because of the very high standards that he demanded of himself, Mandelstam delayed, especially of late, the publication of his researches. For this reason much of his work will not be generally known until the posthumous edition of his collected works, which the Soviet Government has decreed, is published. His scientific researches earned him the Lenin prize, the Mendeléeff prize and the Stalin prize. For his general scientific and teaching work he was awarded the Order of the Red Banner and the Order of Lenin.

Mandelstam was a man of infinite kindness, possessed of great spiritual and intellectual charm that never failed to impress anyone who came into contact with him. Those who had the good fortune to know him more intimately will always cherish the memory of this scientific worker and man.

P. KAPITZA.
A. JOFFÉ.
S. VAVILOV.

WE regret to announce the following deaths:

Mr. R. W. F. Harrison, sometime assistant secretary to the Royal Society, on July 15, aged eighty-seven.

Dr. J. C. Kernot, an authority on adhesives, on July 6, aged sixty-six.

Lieut.-Colonel J. C. Lamont, C.I.E., sometime professor of anatomy at Lahore Medical College, on June 19, aged eighty.

Prof. W. Makower, O.B.E., formerly professor of science at the Royal Military Academy, Woolwich, on July 7, aged sixty-five.

Dr. Catherine A. Raisin, formerly head of the Department of Geology, Bedford College for Women, University of London, on July 13, aged ninety.

Colonel C. H. D. Ryder, C.B., C.I.E., formerly surveyor-general of India, on July 16, aged seventy-seven.

Dr. Alec Sand, F.R.S., physiologist to the Marine Biological Association since 1935, early in July, aged forty-three.

Mr. F. H. Todd, formerly of the Indian Forest Service, on July 9, aged seventy-one.

NEWS and VIEWS

Prof. George Hevesy, For.Mem.R.S.

PROF. GEORGE HEVESY celebrates his sixtieth birthday on August 1 in Sweden, where he is a guest of the Royal Swedish Academy of Science in Stockholm. Members of the Academy have prepared a jubilee volume to mark the occasion. Prof. Hevesy and his family escaped from Denmark to Sweden when racial persecutions in Denmark and the tide of terrorism by the German occupants reached a climax in 1944. Prof. Hevesy is well known especially for his work on isotopes, including the early use of radioactive tracer atoms in investigations on diffusion in crystals and later on numerous biochemical problems, involving among others the study of the metabolism of phosphorus in organisms. His other great field of contributions to modern science is the discovery of the element hafnium, the chemical separation of hafnium from zirconium and the study of the properties of hafnium compounds. The relationship between hafnium and zirconium led him to the problem of the rare earth elements. Later, he developed quantitative analysis by means of his X-ray technique for the study of the geochemical frequency and distribution of numerous elements.

Prof. Hevesy, a Hungarian by birth, has held professorial chairs in Denmark (Copenhagen), in Germany (Freiburg-i.-B.) and from 1934 again in Denmark, where his work has been closely associated with the famous Institute of Theoretical Physics at Copenhagen directed by Niels Bohr. In just recognition of his contributions, he was awarded the Nobel Prize for Chemistry for 1943. He has many ties with scientific men in Britain. For a period beginning in 1911, he worked in the late Lord Rutherford's laboratory when the latter was at Manchester. He frequently visited Britain to attend scientific meetings; and in 1930 he gave the Hugo Müller Lecture before the Chemical Society. A number of British research students worked at his laboratories. Hevesy's many friends in Great Britain and elsewhere will be glad to know that he and his family are well, and will wish him many years of continued successful work and of happiness.

Chair of Geography at Sheffield: Prof. R. N. Rudmose Brown

THE retirement of Prof. R. N. Rudmose Brown from the chair of geography at the University of Sheffield at the end of this session marks the official end of nearly forty years of teaching and guiding university geography. His influence on the subject outside his university has been exercised through his being a member at one time or another of all the more important councils and committees which have to deal with geography, as well as through his books. Though he approached the subject from the point of view of a polar explorer and a naturalist, he has always insisted upon the essential unity of its physical and human aspects. His many contacts with French and other Continental geographers may have been the spur which caused him to become as notable a lecturer and writer on the human and economic aspects of his subject as the biological and physical side. His contribution to the recent advance of academic geography has therefore been based on the broadest grounds. This is reflected in his new building for his Department at Sheffield, which is second to none in Great Britain. Planned by him to serve with equal emphasis all the aspects of modern geography, it is a model which will be copied elsewhere in due course. As counsellor, examiner, writer, editor and practical explorer, Prof. Rudmose Brown has had an influence on geography which will endure. His rugged honesty of purpose and direct speech will be missed in many a council chamber, but it is quite certain that his years of retirement will often be interrupted by requests for advice from his younger colleagues, who will continue to be attracted by his wisdom and breadth of vision as well as by his long experience and commanding personality.

Squadron-Leader David L. Linton

SQUADRON-LEADER DAVID L. LINTON, who succeeds Prof. Rudmose Brown at Sheffield, is thirty-eight years old, and was well known in British geographical science before the War. He had been an exceptionally distinguished student at King's College, London; and after a period on the staff of the Geography Department there, he became a lecturer in geography under Prof. A. G. Ogilvie at the University of Edinburgh. His published researches into the relations between land forms and river drainage brought him (jointly with his collaborator, Prof. S. W. Wooldridge) the Murchison Grant of the Royal Geographical Society; and besides other work on geomorphology he has published studies in historical, general and economic geography. His teaching experience is also wide. Before the War he was secretary to the Geography Section of the British Association, and on the Council of the Institute of British Geographers and that of the Royal Scottish Geographical Society. His service with the R.A.F.V.R., in which he won successive promotion to squadron-leader, has been in photographic intelligence, in which he is in charge of a H.Q. Department.

Fellowships for Scientific Research in India

I.C.I. (India) have offered to the National Institute of Sciences of India the sum of 336,000 rupees (about £25,000) for research fellowships in chemistry, physics and biology, to be held at Indian universities or institutions approved by the Council of the National Institute of Sciences, over a period of five to seven years. Each fellowship will be worth 400 rupees per month and will be tenable in the first instance for two years. There is provision for four new fellowships every year during the period 1945–49. In addition, there will be a grant for research expenses to be made to the fellowship holders according to their needs of special apparatus and materials. For this purpose the National Institute has at its disposal an average of 600 rupees per annum for each fellowship. There will be a grant of 13,200 rupees per annum to the National Institute for five years to enable it to pay for administration and the travelling expenses of such fellows of the Institute as may be selected to visit the fellowship holders at their universities or institutions. Appointment to, and control of, the fellowships will be in the hands of the Council of the National Institute, acting on the advice of a special research fellowships committee, representative of various scientific fields and drawn from various parts of India, so as to include any community, the overriding consideration for membership being scientific fitness therefor. The fellowships will be open to persons, irrespective of sex, race or religion, resident or domiciled in India (British India or the States) and less than thirty-five years of age, and will be tenable at any university or institution in India approved by the Council of the National Institute. Fellows will be permitted to do a limited amount of approved teaching or demonstrating.

The aim of the fellowships is to strengthen research in Indian universities and institutions, and it is hoped that the National Institute of Sciences will spread the research fellowships over them in accordance with this aim, but with the overriding consideration of the scientific suitability of the particular university or institution. As Lord McGowan points out in his letter conveying the offer to the president of the National Institute, these fellowships should do something to encourage the advance of science in India and with it the general prosperity of the country; further, they should assist the National Institute in maintaining its position as the premier scientific body of India. The offer is in many ways parallel with that made to British universities a short time ago by Imperial Chemical Industries, Ltd., and, it may be presumed, is inspired by the suggestions made by Prof. A. V. Hill in his recent report on research in India (see *Nature*, May 5, p. 532).

Education in H.M. Forces

An encouraging feature in the latest report of the Central Advisory Council for Education in H.M. Forces (October 1944–March 1945) is the considerable increase in the number of organized classes as opposed to single lectures conducted in Service units (see *Nature*, 155, 611; 1945). The latter have decreased by some 19 per cent, while the former show the significant rise of 37 per cent. Outside units, the number of intensive schools and conferences also shows a remarkable increase, and it is particularly gratifying that a growing proportion of these schools and conferences are being conducted on a residential basis. It is distressing, therefore, to find that while there is every indication that the demand for intensive courses will increase, there is little likelihood of the demand being met in full unless residential accommodation is made much more freely available. Four university institutions have already lent hostels for whole-time use for regional committee courses, but more help is urgently needed from Service authorities towards the initial cost of reconditioning buildings and also in facilitating the release of suitable premises.

Although the number of occasional lectures in science shows the same downward trend as single lectures in other subjects, the rapid increase in the number of science classes in units is a useful indication of the way in which Service men and women are pursuing their studies with more serious intent; it is noteworthy that there has been a big shift from 'non-vocational' to 'vocational' science. Several background courses in science, lasting a week or a fortnight, have also been held, usually at university centres. One regional committee broke new ground by instituting experimental courses on British industries. The object was to provide unit instructors with background information about the actual structure of some of Britain's major industries and then to discuss some of the problems that the industries would have to face in the future. Lectures were given by specialists on various aspects of the industries considered, while visual and other mechanical aids were used to supplement the teaching and discussion. Visits to works and firms also served to provide the necessary balance between detailed knowledge and general understanding of the broad issues affecting each industry. Other useful work carried out by the Central Advisory Council during the half-year covered by the report was that for soldiers and auxiliaries in hospitals and convalescent homes.

Argentine–British Medical Centre, Buenos Aires

An Argentine–British Medical Centre has been established in Buenos Aires, with the assistance of the British Council, to promote closer relations and to facilitate the exchange of information between the British and Argentine medical professions. The Centre has a Committee of Honour, the twenty-two Argentinian members of which include Prof. José Arce, Prof. Pedro Escudero, Prof. B. A. Houssay and Prof. Alfredo Sordelli. British representatives of various branches of medicine have been invited to join this Committee. On the Executive Committee are the president of the Centre (Prof. Dr. Mariano R.

Castex), the director (Prof. Dr. Antonio Eqües), the secretary (Dr. R. Castro O'Connor), an assistant secretary, three ordinary members, and two representatives of the British Hospital in Buenos Aires. The Centre's library contains a selection of the most important British medical journals and up-to-date text-books. When an inquiry cannot be answered on the spot, the Centre obtains, through the British Council, information, articles and books (or photostat copies) from Britain. Among the activities are distribution of the "British Medical Bulletin" (Spanish edition), supply of medical films, translations from English into Spanish and Spanish into English, and certain facilities for members wishing to subscribe to British medical journals, or buy British medical books. The facilities are available to medical men in the interior of Argentina, who, since they are not in a position to borrow original books and articles, are supplied with photostat copies.

University of London Appointments

The following appointments have been made in the University of London: Dr. D. H. Hey, since 1941 director of research at the British Schering Research Institute, to the University chair of chemistry tenable at the Imperial College of Science and Technology; Dr. F. C. Benham, to the University chair of commerce tenable at the London School of Economics; since 1931 he has been Sir Ernest Cassel reader in commerce at the School. Mr. D. W. Harding, special lecturer in psychology in the University of Manchester, to the University chair of psychology tenable at Bedford College.

Mr. Raymond Irwin, county librarian of Lancashire, has been appointed to the directorship of the School of Librarianship at University College as from October 1.

The title of reader in bacteriology in the University has been conferred on Mr. J. C. Cruickshank, in respect of the post now held by him at the London School of Hygiene and Tropical Medicine.

The degree of D.Sc. as an internal student has been conferred on the following: Mr. C. R. Bailey (University College); Mr. R. V. Harris (Imperial College of Science and Technology); Mr. G. W. Padwick (Imperial College of Science and Technology); Mr. L. Young (University College and Imperial College of Science and Technology).

The Night Sky in August

New moon occurs on August 8d. 00h. 32m. U.T., and full moon on August 23h. 12h. 03m. The following conjunctions with the moon take place: August 2d. 23h., Mars 2° N.; August 4d. 16h., Venus 1° S.; August 5d. 23h., Saturn 1° S.; August 9d. 07h., Mercury 9° N.; August 11d. 06h., Jupiter 4° S.; August 31d. 13h., Mars 0·9° N. In addition to the conjunctions with the moon, Venus is in conjunction with Saturn on August 22d. 04h., Venus being 0·7° S. Only one occultation of stars brighter than magnitude 6 takes place in August; ξ Tauri is occulted on August 4d. 3h. 28·9m. Mercury sets at 20h. 18m. at the beginning of the month—half an hour after sunset—and is not well placed for observation. The planet is stationary on August 5 and 29 and is in inferior conjunction on August 20. Venus is conspicuous in the eastern sky, rising at 1h. 11m., 1h. 22m. and 1h. 50m. at the beginning, middle and end of the month respectively. Mars, in the constellation of Taurus, rises at 23h. 47m., 23h. 20m., and 22h. 54m., at the beginning, middle and end of the month respectively. Jupiter sets about 1½ hours after the sun at the beginning of August and less than three-quarters of an hour after the sun at the end of the month, and is not well placed for observation. Saturn can be seen in the early morning hours, rising at 2h. 37m. and 0h. 56m. at the beginning and end of the month. The Perseid meteors reach their maximum about August 10–12; the radiant is at R.A. 3h., dec. 45° N., close to κ Persei.

Announcements

Prof. H. M. Turnbull, director of the Pathological Institute of the London Hospital and professor of morbid anatomy in the University of London, has been given the honorary degree of D.Sc. of the University of Oxford.

Prof. A. C. Hardy, regius professor of natural history in the University of Aberdeen and honorary director of oceanographical investigations in the University College of Hull, has been appointed Linacre professor of zoology and comparative anatomy in the University of Oxford, in succession to Prof. E. S. Goodrich.

Dr. Irene Manton, lecturer in botany in the University of Manchester, has been appointed professor of botany in the University of Leeds, in succession to the late Prof. J. H. Priestley.

Mr. A. B. Hornblower, honorary general secretary of the London Natural History Society, has resigned the position he has held for the past sixteen years, owing to ill-health. Mr. H. A. Toombs of the Geological Department, British Museum (Natural History), Cromwell Road, S.W.7, has been appointed to take his place; particulars of the Society's activities can be obtained from him.

The Minister of Town and Country Planning, Mr. W. S. Morrison, has appointed the following National Parks Committee: Sir Arthur Hobhouse (*chairman*), Lieut.-Colonel E. N. Buxton, Mr. John Dower, Mr. Leonard K. Elmhirst, Mr. R. B. Graham, Dr. Julian Huxley, Mrs. Lindsey Huxley and Mr. Clough Williams-Ellis.

The following have been elected officers of the Institution of Electrical Engineers for the year beginning on September 30: *President:* Dr. P. Dunsheath; *Honorary Treasurer:* Mr. E. S. Byng; *New Members of Council:* Mr. L. H. A. Carr, Mr. J. G. Craven, Mr. J. Eccles, Mr. H. Faulkner, and Prof. Willis Jackson (members); Dr. J. M. Meek (associate member); Mr. A. F. Plummer (associate).

The report of the proceedings of the nineteenth conference of the Association of Special Libraries and Information Bureaux, December 9 and 10, 1944, has now been published by the Association, price 6*s*. The report includes the papers presented at the Conference together with summaries of the discussions, the presidential address of Sir Frederic Kenyon, a report of the year's work of the Association, 1943–44, reports on the work of the British Council and on the Inter-allied Book Centre evolved by the Conference of Allied Ministers of Education, with brief notes on the British Union Catalogue of Periodicals and on the National Central Library.

Regeneration of Mammalian Striated Muscle

SINCE the classic studies of Volkmann[1] there has en abundant experimental work which shows that. owing local injury, mammalian striated muscle is able of some degree of regeneration. But this enerative capacity is commonly held to be limited extent and abortive so far as functional repair is ncerned. It can now be stated that, under certain nditions, the regeneration of striated musculature y be much more extensive and complete.

Previous work which has been reported from this oratory[2] showed that if the main vessels supplying e tibialis anterior muscle of a rabbit are ligatured, e lower half or two thirds of the muscle can usually effectively devascularized and undergoes comete necrosis except for isolated fibres at the surface d alongside main anastomotic vessels, and some res at the lower end adjacent to the tendon. Moreer, it was found that within a few days the necrotic uscle becomes invaded by granulation tissue conining new muscle fibres of embryonic type which ream down from the ends of the surviving fibres the upper part of the muscle.

Further experiments have now been completed in rder to determine the fate of these regenerating bres. In two rabbits, the tibialis anterior muscle f both sides was effectively devascularized. Two ays later the muscles were exposed and bromohenol blue injected into the ear vein to determine he exact extent of the devascularization. In both ases the upper third of the muscle became stained n the normal manner, while approximately the lower wo thirds remained unstained, with a sharp line of emarcation between the two parts of the muscle. After three weeks the muscle was resected from one ide for histological examination. In each case the riginal muscular tissue in the lower two thirds was ound to have undergone practically complete dissoluion, and to be replaced in great part by strands of newly formed fibres extending down from above. The muscle of the other side was removed after three or four months. In one case it was somewhat shrunken and showed histologically patches of fibrosis and fatty infiltration in the lower two thirds, but there was also a considerable amount of mature muscular tissue. In the other case the muscle appeared quite normal to superficial inspection, and was found histologically to be composed of muscular tissue of approximately normal mature structure. It thus appears that in the rabbit the lower half or two thirds of the tibialis anterior can become completely reconstituted after undergoing ischæmic necrosis.

These experiments have provided abundant material for the study of the histogenesis of regenerating striated muscle, and this is now being undertaken. It may be said, however, that the material provides no support for the contention of Levander (recently expounded in *Nature* and elsewhere[3,4]) that in the course of the regeneration of mammalian muscle new muscle elements arise by the differentiation of generalized connective tissue cells; on the contrary, they appear to be formed entirely as outgrowths of pre-existing muscle fibres, thus confirming the conclusions of many other students of muscle regeneration.

Levander's conclusions seem to be based on an erroneous interpretation of the histological picture. In our material we have frequently seen the appearance of isolated 'myoblasts' arranged, as he describes, like a shoal of fish in the granulation tissue. But if these are examined by serial sections, the appearance is found in all cases to be due to the oblique sectioning of long continuous strands which can be ultimately traced without interruption to the stumps of pre-existing fibres. If there has been much distortion of the tissues (as has evidently occurred in Levander's material, in which necrosis was induced by the intramuscular injection of alcohol), the connexion between the young fibres and pre-existing fibres may not be easy to establish without the detailed study of large numbers of serial sections. Levander also supports his interpretation by the appearance of young muscle fibres in the neighbourhood of pieces of muscle transplanted into the subcutaneous tissue. He assumes that the original fibres of the transplant undergo complete necrosis. In fact, we have found that in such transplants some of the muscle fibres at the surface may survive and retain their vitality. Moreover, it should be noted that the outgrowth of new muscle fibres from old fibres proceeds with great rapidity. Their maximum rate of growth is at least 1 mm. a day.

Thus *individual* sections may show newly formed fibres at some distance from the position of pre-existing fibres, suggesting an independent origin. Our experiments do not, of course, exclude the possibility of such an origin, but this can only be established by experiments of a more critical character.

Motor Response from Giant Fibres in the Earthworm

IT has recently been shown[1,2,3] by action potential records from the giant fibres that these form two systems; the two laterals are interconnected and act in unison independently of the median. Since the discharge from either fibre system may produce the sudden end-to-end shortening of the worm, the question arises why the nerve pathway is double. Stough's answer[4,5] that the median giant will only conduct backwards and the laterals forwards is incorrect, for their action potentials can be shown normally to run both ways[1,3].

A new fact emerges, however, for the sensory field of the median giant is found to be mainly from the first forty segments, and for the laterals from the remainder of the worm (at least in the conditions of the experiments). So it is natural to look for a difference in the two motor responses adapted to escape from attack at the head or at the tail respectively. This is the case.

If the worm is on a slippery surface, the giant fibre response when either head or tail is touched is a shortening towards the middle because (from mechanics) the centre of gravity cannot move. But if the worm is placed on a damp sack where the setæ can grip, it immediately appears that responses are of two kinds. Either the tail is anchored and the head withdrawn, or the head is fixed and the tail brought forward. The first reaction results from touching anterior to the fortieth segment, the second from the region posterior. The protective significance of these responses and their correspondence with the giant fibre sensory fields is obvious.

One other difference in the two responses is easy to see in *Lumbricus*. The median response is accompanied by a characteristic flattening of the tail, the laterally extended edges of which bristle with large setæ directed forward. This reaction is well adapted to grip the sides of the burrow within which the tail usually rests when the worm emerges at night. In the lateral giant fibre response, the tail becomes thin and round in section; hence the two responses are readily distinguished even on slippery surfaces.

Now when at night the worms are extended on the ground with only the tail region in the burrow, they may easily be touched or seized posterior to the fortieth segment. From what has been said it is clear that they should exhibit the lateral giant response, grip with the head and instantly come out of the burrow. This suicidal response never occurs; the worm always appears to exhibit the median giant response, and this no matter what part of the surface is touched.

Clearly observations in the field show a wider range of central connexions than are commonly found under the conditions of electrical recording. It seems that the presence of the tail in the burrow causes some switching over between the two systems. Either the median normally has potential sensory connexions with the body, posterior to segment forty (as indeed some records actually show[3]), which become functional when the tail is in the burrow, or else this attitude causes the lateral giants to activate the motor system used only by the median when the worm is free on the surface. Further observations are needed to settle these and other possibilities.

Cell Contents of Pus

FROM our previous studies entitled "Cell Contents of Milk"[1] we arrived at the conclusion that the fat in milk is secreted by a kind of polymorph neutrophil; as a sequel to this we have investigated the cell contents of pus.

The pus was collected from both acute and chronic cases, and we made wet and dry films, staining as before with methylene blue and May-Grunwald-Giemsa respectively.

We found that, as with milk in the wet films, we could divide the cells into the following three groups.

(1) The group formed by a majority of polymorph neutrophil cells, in pus specimens from acute abscesses. Some of these polymorphs were full of vacuoles which resembled, in some cases, the fat droplets in milk, but the size of the vacuoles varied considerably (Fig. 1).

(2) The second group consisted of mononucle but in the acute pus there was a noticeable abse of the very large cells we found so easily in the n and thyroid fluid. Some of the mononuclears in group contained vacuoles of different sizes, some them being the size of red blood corpuscles.

(3) In the third group are the small mononucle In the chronic abscesses the majority of cells w lymphocytes, which could be seen attached to or two small vacuoles, similar to the lymphocy we found in milk (Fig. 2).

In the dry films also we were able to classify cells, but as in milk, the cells were not in th distinctly different groups, but were linked intermediate cells.

(1) In the first group were numerous polymor containing a large number of empty vacuoles o uniform size. There were also polymorphs w nuclei which appeared to be under pressure becau of the growing vacuoles of different sizes, some them being almost as large as red blood corpuscl These vacuoles appeared to be empty, as the mater contained in them had probably been dissolved the alcohol used in the stain (Figs. 3–5).

(2) The second group contained a wide range mononuclears, and occasionally a very large mon nuclear could be found which had a bluish cytoplas full of empty vacuoles. These mononuclears appear to be very fragile and a large number of the had been broken by the smear (Figs. 6 and 7).

(3) The third group consisted of lymphocytes, a when the dry smear was made from tuberculous pu it could be observed that the lymphocytes still r tained two or three vacuoles in their cytoplas (Figs. 8 and 9).

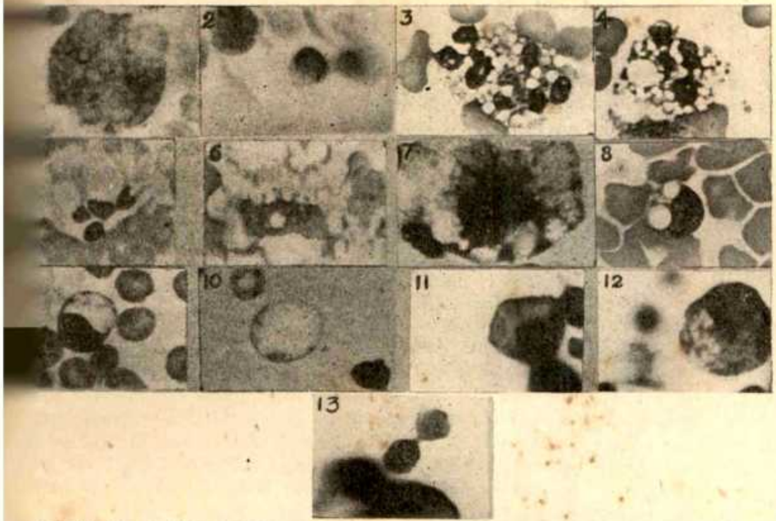
As mentioned above, in all the specimens of p examined there was a noticeable absence of the hu mononuclear cells we had observed in milk and cyst fluid from the thyroids. This can be explained the fact that the pus is not sterile, and includes its composition some very toxic products fro bacterial metabolism and from tissue necros which probably interferes with the full developme of the cells, and consequently there is an absence cells of large size. There are also found in the p some cells which set free portions of their prot plasm, as was observed in milk, and in the same w the liberated portions take on the form of roun drops. Some of the free cytoplasmic portions st framed empty vacuoles (Fig. 10).

Having now confirmed the similarity betwe milk and pus by wet films and dry smears, we studie the histological morphology of different abscesses different tissues.

In sections of granulomas, stained by hæmatoxyl and eosin, and under oil immersion, we were ab to observe a whole range of cells. It was simple follow the evolution from a polymorph neutrop to a larger cell which has been described as a 'foa cell' or lipo-macrophagic cell, then to a small mon nuclear and finally to cells which are similar to t plasma cells. The cells eventually revert to lymph cytes (Figs. 11–13).

The huge mononuclear cells we have observed the milk were also found in the granulomas. Th are present in the edges of the necrotic tissue a not in the pus itself, and this had not interfered wi their development. Occasionally an odd one or tw of these extra large cells float into the pus, only break out and be destroyed when the pus is erupte

It is clear that these large mononuclears prese



WET FILMS. 1. A POLYMORPH FILLED WITH WHAT APPEARS TO BE FAT GLOBULES. 2. A LYMPHOCYTE STILL ATTACHED TO A FAT DROPLET.
SMEARS STAINED WITH MAY-GRUNWALD-GIEMSA. 3, 4. POLYMORPH NEUTROPHILS FULL OF VACUOLES. 5. POLYMORPH CONTAINING LARGE VACUOLES, SOME OF THEM ALMOST AS LARGE AS A RED BLOOD CORPUSCLE. 6. INTERMEDIATE CELL BETWEEN A POLYMORPH AND A MONONUCLEAR. 7. A HUGE MONONUCLEAR FULL OF VACUOLES. 8, 9. LYMPHOCYTES FULL OF VACUOLES. 10. PROTOPLASMATIC REMNANT FRAMING PUS DROPLETS.
FROM GRANULOMA, STAINED WITH HÆMATOXYLIN AND EOSIN. 11, 12, 13. SHOWING THE EVOLUTION OF CELLS IN THE GRANULOMA.

the granulomas originate from a polymorph neutro-il, for they are only an intermediate stage between e polymorph and the lymphocyte, passing naturally rough the stage of mononuclear.

I must thank my technician, Mr. Jeffrey B. Dean, r preparing the photomicrographs.

Conclusions. From our studies of different pus ecimens and granulomas we have formed the llowing conclusions.

(1) The presence of leucocytes is necessary for the rmation of pus, and the pus is not produced from he same tissue in which the inflammatory process is resent, a fact which is already well known.

(2) The material collected and known as pus is a roduct of secretion by the polymorph neutrophil.

(3) The cell which secretes the pus is the poly-norph neutrophil, which by changing its size and uclear structure expels its products and becomes mononuclear, eventually becoming a lymphocyte.

(4) This monoglandular cellular mechanism of pus ecretion is similar to the process of milk fat secretion nd the process seen in the cystic fluid from the hyroid glands.

Heat Injury in Insects

IN an article on the hardening and darkening of the insect cuticle, Dennell[1] pointed out that both tyrosine and tyrosinase are present in the hæmolymph of late blow-fly larvæ (for example, of *Sarcophaga falculata*), but that darkening does not occur unless the blood is exposed or the larvæ treated with various substances. He went on to suggest that this inhibition *in situ* may involve the action of an unidentified dehydrogenase, the destruction of which results in the onset of tyrosinase activity.

It seems opportune, in this connexion, to give a brief preliminary account of some work on heat injury in blow-fly larvæ (*Sarcophaga falculata* and *Calliphora erythrocephala*). It was found that with a sufficiently refined technique employing short (three-minute) exposures, fully grown larvæ could be so injured by heat that although they recovered from heat dormancy and appeared normally active, death occurred within a few days. The basal oxygen uptake of such larvæ, as compared with untreated controls, showed a considerable increase, accompanied by browning of the tissues, from about a day after treatment.

This seems to indicate tyrosinase activity, which would be in agreement with Dennell's suggestion since dehydrogenases might well be affected by heat treatment. Dennell's original suggestion mentions "tyrosine being reduced as rapidly as it is oxidized" and would seem to involve the continuous oxidation of some reducing substrate in the blood. On this basis there is no reason to expect an *increase* of oxygen uptake to result from destruction of the dehydrogenase. However, Dennell informs me in a private communication that his more recent work on the electrode potential of the hæmolymph indicates that no oxidation of tyrosine takes place until the inhibiting factor in the blood is eliminated. From this it would be expected that in larvæ injured by heat no increased oxygen uptake should be observed until darkening occurs, and these later results agree closely, therefore, with the present observations. Hopf[2] mentions the possibility of heat injury producing enzyme activation in the hæmolymph. Whatever the precise explanation, however, the effect seems to be an upsetting of enzyme balance in the tissues.

Preliminary investigation (mainly by supra-vital staining) of the mitochondria of the fat-body of *Calliphora* larvæ seems to indicate that while those of treated larvæ are small discrete globules, those of controls are generally larger and often aggregated into clumps. If further work confirms this difference, it will be a matter of some interest, as it may well be the mitochondria which first suffer injury by heat.

The various theories of heat injury have been reviewed by Belehradek[3], but only the 'enzyme' and 'lipoid liberation' theories need be considered here. The former proposes that heat injury is due to the inactivation or destruction of enzymes, and seems to have some relevance to the present problem, where heating results in an upsetting of enzyme balance. The widely held 'lipoid liberation' theory postulates the 'liberation' of protoplasmic fats as the cause of heat injury. Among more recent work, that of Fraenkel and Hopf[4] on *Calliphora* and *Phormia* larvæ, while not completely supporting the theory, produced some evidence in its favour.

The mitochondria as the possible site of heat injury provide a link between these theories. They are thought to be bound up intimately with enzyme activity (see reviews by MacBride and Hewer[5], and Bourne[6]), and it is also generally agreed that lipoidal complexes play an important part in their chemical structure (see Bourne, *loc. cit.*). The 'liberation' of mitochondrial lipoids, therefore, might well result in an upsetting of the enzyme systems of an animal and lead to irreversible heat injury. There is evidence in the literature that heat can cause a break-up of mitochondria in a wide range of organisms including plant cells, frogs, fish, guinea pigs and rabbits (see references in Belehradek[3], and MacCardle[7]). It seems possible, therefore, to suggest tentatively that heat injury is due primarily to a break-up of mitochondria and a consequent disruption of enzyme balance. In the case of fully grown blow-fly larvæ, if a dehydrogenase system is truly involved in preserving this balance, its inactivation during heat injury may be through the mitochondria rather than a direct effect of heat.

Part of the work mentioned above was carried out some time ago at the Imperial College of Science and Technology, London. It will be continued, and full details published elsewhere.

Mode of Entry of Contact Insecticides

INVESTIGATIONS now being carried out by us into the use of D.D.T. for the elimination of tsetse (*Glossina* spp.) have led to observations which have a bearing on the mode of entry of some contact insecticides. This problem seems generally to have been considered only in connexion with the usual methods of using contact insecticides, in which the object is to bring the poison, either by spraying or by dusting, into maximal contact with the general body surface of the insect. Mr. Napier Bax has pointed out to us an exception to this, for Tutin[1], so long ago as 1928, does record an observation in which two Carabid beetles and a Cicindelid died after being placed in a dish previously sprayed with an emulsion containing a rape-oil solution of pyrethrum, after the emulsion had dried. Nevertheless, no general attention seems to have been paid to the mere contact of insects with a sprayed surface. Thus Roy and Ghosh[2], discussing as recently as July 1944 various views on the mode of penetration of pyrethrum, and particularly those of Wigglesworth[3,4], record observations which led them to the conclusion that pyrethrum normally enters the insect body through the spiracles.

Our approach has been along the lines of Tutin's observation and therefore somewhat different from the one generally adopted; thus tsetse have been brought into contact with D.D.T.- and pyrethrum-covered surfaces through the feet only, flies being allowed to sit on the prepared surface or held over it with just their feet touching, for various specified periods. Contacts as short as five and even two seconds have proved fatal. One of us (F. L. V.) has demonstrated the presence of particles of D.D.T. on the pulvilli of flies so treated, and from observations on insects with varying degrees of pulvillar development it appears that the action of t
poisons is more rapid when the pulvilli are
developed. Death has followed in the case of D.I
after intervals of half an hour or more, so that
we cannot completely dismiss the possibility
carriage of the poison to the spiracles from the pul
in the flies' efforts to rid themselves of the irritat
particles. But death from pyrethrum has been
graphically rapid that no such explanation is t
able; thus repeatedly tsetse given a few seco
contact with the pyrethrum-treated surface h
become completely paralysed in the interval betw
the removal of the fly from the poisoned surface
the handing of its tube to the recorder for marki
This rapid 'knock-down' action of pyrethrum is,
course, well known, but wears off so rapidly that
contact effect has not much practical applicatic
it is the enduring quality of D.D.T.'s insectici
principle that opens up possibilities of using
contact effect in a practical manner.

The experiments referred to have been carried o
on the haired surface of small pieces of dried cat
hide treated with various strengths of D.D.T. (a
pyrethrum) combined with various adhesive solutic
(such as local gum, serum, wax, resin, etc.) and l
to dry; it is therefore unlikely that any emanati
entering through the spiracles can be held respc
sible for the effect, but further experiments are
be carried out. It is also very noticeable, pa
ticularly with the slower acting D.D.T., that t
first symptoms of actual distress, apart from cleansi
movements of the legs somewhat more persiste
and continuous than usual, are convulsive movemen
of the legs, which suggest that their nervous contr
is the first activity to suffer interference.

Work is proceeding, but these observations
suggest that certain insecticides need not necessari
be applied in such a way as to bring about eith
penetration of the general body cuticle on a larg
scale, or entry through the spiracles; but that the
action can be equally effective through contact
the feet alone, at any rate in species with wel
developed pulvilli.

Congo Red Fibrin Powder for Experiments on Proteolytic Enzymes

STAINED fibrin substrates are sometimes used for experiments on proteolytic enzymes. Grutzner[1] used fibrin stained with carmine to estimate the amount of pepsin in a solution. Carmine fibrin cannot be used for testing for trypsin as the dye is dissolved out of the fibrin by alkalis. The difficulty was overcome by Roaf[2], who as early as 1908 used Congo red instead of carmine. Congo red is not dissolved out of the stained fibrin by hydrochloric acid or by sodium carbonate, and can thus be used for experiments on both trypsin and pepsin. Roaf first used a moist preparation which was preserved in equal parts of glycerol and water to which a little toluene was added. Later[3] he used Congo red fibrin in the form of a dry powder, in which condition it kept well. Very little attention seems to have been paid to Roaf's work. Cole[4] describes the use of carmine fibrin for an experiment on pepsin but does not mention Congo red fibrin. Hawk[5] suggests the use of carmine fibrin for pepsin and Congo red fibrin for trypsin. These are both moist preparations which have to be preserved under ether or glycerol. The advantages of a dry stable powder which can be used for both pepsin and trypsin are obvious.

About a year ago, unaware of Roaf's work at the time, we prepared a Congo red fibrin powder which has proved very satisfactory for students' experiments on proteolytic enzymes. Our method of preparing the powder is similar to Roaf's method.

The powder has been incubated at 37·5° C. for twenty-four hours in 0·2 per cent hydrochloric acid and in 0·5 per cent sodium carbonate without any of the colour coming out. Incubation at 37·5° C. in 0·05 per cent sodium hydroxide, however, resulted in a faint pink colour at the end of one hour. Peptic digestion gives a blue violet and tryptic digestion a red solution.

Preparation. (1) Wash some fresh fibrin in running tap water for several minutes. Transfer to a beaker of water and heat to about 70° C., stirring at intervals. Strain through muslin and rinse well in running water. (2) Mince the fibrin and put in slightly alkaline Congo red solution (450 c.c. distilled water; 50 c.c. 96 per cent alcohol; 0·2 c.c. 2 per cent ammonia; 2·5 gm. Congo red. 500 c.c. is used for every 100 gm. fresh moist fibrin). Heat to 80° C., stirring at intervals. Strain through muslin and wash in running tap water. (3) Place in a beaker of water which has been made alkaline to phenolphthalein by the addition of 2 per cent sodium carbonate. Heat to about 70° C., stirring at intervals. Strain and wash thoroughly in running tap water until the washings are colourless. (4) Spread the stained fibrin on filter paper and dry in an oven at 60° C. (5) Grind to a powder in a mortar. (6) Cover the powder with acetone and stir at intervals for five minutes. Pour off the acetone, spread the moist powder in a thin layer on filter paper and allow to dry.

About 10 gm. of powder are obtained from 100 gm. of fresh moist fibrin.

Action of Mepacrine on Diamine Oxidase

THE observation by Hammick and Chambers[1] that 2-chloro-5-amino-7-hydroxyacridine is a breakdown product of mepacrine found in human urine shows that the side-chain of mepacrine is removed by the scission of a C—N linkage.

In this connexion it seems of interest that the drug has a marked affinity for the enzyme diamine oxidase. Using an acetone-dried preparation of pig's kidney and $5 \times 10^{-3} M$ cadaverine as substrate, we find that mepacrine depresses the oxygen uptake due to oxidation of cadaverine. The inhibition with $10^{-3} M$ mepacrine dihydrochloride was 92 per cent, with $10^{-4} M$ and $10^{-5} M$, 82 per cent and 45 per cent respectively.

The affinity of mepacrine for the enzyme is only in part due to the presence of the side-chain. In an experiment in which mepacrine was compared with 2-chloro-5-amino-7-methoxyacridine (kindly given to us by Dr. D. Ll. Hammick and S. F. Mason), that is, the compound corresponding to mepacrine without the side-chain, the inhibitions—in $10^{-4} M$ concentration—were 70 per cent with mepacrine and 33 per cent with the amino derivative.

Effect of Alpha-Ray Bombardment on Glide in Metal Single Crystals

THERE are many indications that surface imperfections of the crystal lattice play a marked part in the initiation of the glide that results when single crystals are subjected to stress. Orowan[1] and others have discussed the matter from the theoretical side. From the experimental side, Roscoe[2], working in my laboratory, has shown that a very thin oxide film on the surface produces an increase in the resistance to plastic deformation, which cannot be due to the cohesion of the film, and Rehbinder[3] has shown that very thin surface films of certain substances, applied to single crystals, produce striking effects.

In order to throw light on the part that the surface plays in glide, I have been bombarding stressed single-crystal wires of cadmium with α-rays from a strong polonium source, deposited on the inside of a nickel cylinder 1 cm. long, which is split longitudinally so that it can be made to surround the wire. It was thought that the intense temperature agitation produced by the impact of a particle would, when the particle struck the metal in the immediate neighbourhood of a minute surface crack or dislocation, initiate glide. The α-particles, which penetrate about 0·005 mm. into the metal, cause considerable local disturbance, but under the experimental conditions do not produce appreciable bulk heating. Direct experiment proves that with my disposition the rise of temperature at the axis of the wire does not exceed 0·01° C.

The preliminary results of these experiments show that when a wire is stressed so as to produce a slow creep, of the order of 0·05 per cent per minute, bombardment with α-particles causes the rate of flow to increase to several times the value which obtained before the bombardment—five times in one particular case—although the wire was bombarded over only one third of its length. The wire had been extended by about 1 per cent when the bombardment was initiated. In the case of another wire which had been extended by 2·6 per cent of its length, and was increasing its length at a rate of 0·21 per cent per minute, bombardment increased the rate by about three times.

The greater the preliminary extension which had taken place before the bombardment, the smaller the effect of the α-particles. After an extension of 3 per cent, when the rate of flow was markedly decreasing owing to the usual hardening effect, the bombardment caused but a small, although definite, change in the rate. With a wire that had been extended by 12 per cent, and was flowing at the rate of 0·7 per cent per minute, bombardment did not affect the rate of flow. Incidentally, this confirms that there is no appreciable bulk heating.

The above figures are given as indications that the effect is considerable: no precise quantitative significance is to be attached to them, since the strength of the source has not been accurately measured nor the inclination of glide plane and glide direction determined. Owing to the destruction of this laboratory during the air attacks, facilities are at present lacking for any such measurements. What the experiments show clearly, however, is that glide on particular planes can be initiated by α-ray bombardment, and hence that initiation of glide takes place from the surface. Once a particular plane is active, glide continues at a rate independent of the surface disturbance, as shown by the fact that bombardment does not affect the rate after large preliminary strain when, presumably, all suitable glide planes are in action. The α-particle bombardment is, then, a useful index to show whether glide is taking place by the activation of new glide planes or is continuing on planes already in action. In this connexion it can also be made to throw light on the mechanism of hardening, as discussed, for example, in a paper by Andrade and Chow[4].

A New Approach to Relativistic Cosmology

THE kinematical part of relativistic cosmology concerns the most general line-element which satisfies the conditions of homogeneity. It has the form

$$ds^2 = d\tau^2 - R^2(\tau)d\sigma^2 \quad . \quad . \quad . \qquad (1)$$

where $d\sigma^2$ is the line element of a three-dimensional space of constant curvature k: 1, 0, − 1.

It is *always* possible to change (1) into the form:

$$\begin{gathered} ds^2 = \gamma\,(r,t)(dt^2 - dx^2 - dy^2 - dz^2) \\ r^2 = x^2 + y^2 + z^2 \end{gathered} ; \quad . \quad . \qquad (2)$$

The form (2) is more general than (1) and to make (2) equivalent to (1) requires additional restrictions concerning γ. It would seem that the transition from (1) to (2) is purely formal, and that nothing can be gained by a discussion of cosmological problems on the metrical background (2) instead of (1). However, this is not so. To show it we shall formulate some conclusions following immediately from (2):

1. The light geometry of any cosmological space (in (2)) is identical with that of a Minkowski space.

2. Any cosmological space can be looked upon as a Minkowski space with a non-Minkowski gauging. This is clear if we regard γ as the gauging factor in Weyl's sense. Thus, the most general cosmological space can be pictured as a Minkowski space in which the length of a vector changes by transportation, though in an integrable way.

3. The solution of Maxwell's equations in a cosmological space is identical with that in a Minkowski space. This can be deduced from the gauge invariance of Maxwell's equations, or from the fact that neither f_{kl} nor $\sqrt{-g}\,f^{kl}$ nor the structure of Maxwell's equations contains γ. The radiation spreading through the zero-cone is insensitive to any changes in γ. This simple conclusion seems to be unknown. Until recently papers were written on the solution of Maxwell's equations in a cosmological world. What the authors really found was a solution in a Minkowski space complicated by the choice of a co-ordinate system convenient for the description of motion of particles but very inconvenient for the description of an electromagnetic field.

4. The same holds true for Dirac's equations. They are, like Maxwell's equations, insensitive to the choice of γ. Or, rather, they must be expressed in a form such that they will be gauge invariant in the above sense. Again, papers dealing with Dirac's equations in a cosmological space give results apparently different from the old ones because of an inconvenient choice of a co-ordinate system.

Infra-Red Spectrum of the Night Sky

WE photographed the infra-red spectrum of the night sky by means of a spectrograph with two prisms having an aperture of $f/1 \cdot 5$, giving a dispersion of 2000 A./mm. near 8000 A. and of 3000 A./mm. near 10000 A. We used the only infra-red plates we had at our disposal, namely, "800" AGFA plates; we sensitized them before exposure. A ten-hour exposure made at the end of February 1942 at the Lyons Observatory gave us a spectrum[1] showing:

(1) A broad band without any visible structure, stretching from λ 7400 A. to about λ 8500 A., with a notable fall of intensity beyond λ 8200 A.; according to the earlier observations made by Cabannes[2], it appears to be the first positive system of the nitrogen bands, the *A* oxygen band and the water-vapour bands.

(2) A very broad band at about 0·97 μ and a line or band about 1·03 μ. Since the limit of sensitivity of the plates we used is normally about 0·85 μ, an image much beyond 0·9 μ is possible only if there is in the night sky an unusually intense emission in this spectral region.

The broad band about 0·97 μ is probably the 0·94 μ water-vapour band. As to the 1·03 μ radiation, we considered two possible origins: either the (0,0) band of the first positive system of the nitrogen bands (wave-length of the head, 1·042 μ) or the forbidden doublet $^2P - {}^2D$ of the N I atom (λ 10410 A.–λ 10401 A.). In fact, on one hand, the (0,0) band of the first positive system can quite well be seen alone in the infra-red region observed because of its strong relative intensity[3]; the existence of the (0,0) band of the first positive system would fit in with the fact that most of the bands of this system have been found both in the visible and in the distant red[2]. As to the infra-red [N I] doublet, we have just heard through a private letter from an American colleague that its permanent presence in the spectrum the night sky has been indicated recently, and at its intensity would exceed that of the green line [O I]. This fact, important for the physics of the pper atmosphere, confirms the ideas recently exunded by one of us[4], who showed that nitrogen ust be found essentially in the atomic state in the pper atmosphere. But it remains possible that the vo identifications that we suggest may be simulneously true; moreover, the two emissions may e bound together by a mechanism one of us has ready pointed out[5]: the (0,0) band of the first ositive system corresponds to the $B_0 - A_0$ transition f the nitrogen molecule; now the presence of the egard-Kaplan bands in the radiation of the night y leads us to admit the presence of numerous A_0 olecules in the upper atmosphere; through the ollision between the A_0 molecules and the ^2P atoms e can have the following process:

$$\underbrace{\overset{A_0}{6{\cdot}14\text{ v.}} + \overset{^2P}{3{\cdot}56\text{ v.}}}_{9{\cdot}70\text{ v.}} \rightarrow \underbrace{\overset{B_0}{7{\cdot}32\text{ v.}} + \overset{^2D}{2{\cdot}37\text{ v.}}}_{9{\cdot}69\text{ v.}}$$

Behaviour of Ultra-Violet and Daylight Rays in the Solar Cycle

WHEN graphs are constructed, for the sunspot cycle 1933–44, of the annual averages both of ultra-violet and of daylight rays, they are found to have a decisive *minimum* at the sunspot *maximum*, of 1937–38, and the drop from maximum to minimum of the daylight curves is approximately twice as large as that of the ultra-violet curves. This drop of the rays received at the time when the sun has its highest activity, as shown by the maximum number of spots, suggests that the rays emitted from the sun are in part absorbed in their passage to the earth by some agency which fluctuates with the sun's activity and is most effective at the time of maximum sunspots. The ionization of the upper air due to ultra-violet rays is a probable agency in producing this effect.

While the daylight rays show an inverse relation to the sunspot curve and have a period the same as the sunspots, the ultra-violet rays exhibit two weak maxima on either side of its minimum and the curve appears to have a double period in the solar cycle. An explanation of these observations can be given on the following lines.

As regards the daylight rays, if they are not subject to any large fluctuations on emission from the sun, but are impeded in their passage to the earth by an agency of period like that of the sunspots, such as ionization of the upper air, they will have a single period in sympathy with the solar cycle. If, on the other hand, rays such as ultra-violet rays coming from the sun are subject to sunspot activity and fluctuate with it, and if these rays generate the fluctuating ionization already referred to, which at the same time acts as an absorbing agent, then the ultra-violet rays received on the surface of the earth would at first *increase* with growing sunspots; but at an early stage in the cycle the impeding ionization would reduce their intensity and a point would be reached when they would begin to *diminish* and continue to do so as far as their minimum when ionization is greatest; after which a reverse action would ensue, the rays would *increase*, due to reduction of ionization, and at a later stage they would diminish as their emission from the sun fell off, and two weak maxima would be presented one on each side of the droop of the curve. Thus the single period of the daylight rays coinciding with the period of the solar cycle would be explained by the emission of rays nearly constant over the solar cycle, while the double maximum of the ultra-violet rays would occur if the rays are not emitted uniformly but are subject to a fluctuation in sympathy with the sun's activity.

One result of this point of view is that at an early stage and again at a later stage in the solar cycle the received daylight and ultra-violet rays should move in opposite directions. In the latter part of the solar cycle of 1933–44 this comes out clearly, daylight rays increasing and ultra-violet rays decreasing simultaneously.

At the present time, sunspots are a minimum and there will probably be a rapid increase in their number in the next three or four years. These years will be of the highest interest in verifying or, if necessary, modifying the conclusions derived from the observations made during the solar cycle of 1933–44.

Inverse Binomial Sampling

IN a recent communication discussing the application of the sampling method described by Haldane[1], Tweedie[2] states that the method was described as a technique for using hæmocytometers. This is not so. Hæmocytometers are designed for estimating the population density per unit volume, and the method under discussion is adapted for estimating the incidence of an attribute in a population consisting of members possessed of that attribute and members not possessed of it. This is an entirely different problem. The method, which has been in use in this Laboratory for a considerable time, and has proved of great value, was designed for estimating the incidence of certain abnormal forms of erythrocytes in blood films, this incidence often being as low as 0·2 per cent. By using this sampling technique, increased accuracy is obtained at these low incidence levels, and a saving of time and labour occurs at high incidence levels.

As both Haldane and Tweedie indicate, the method has much wider applications than to hæmatological estimations, but it does not extend to the hæmocytometer type of sampling.

Geology of the Nubian Sandstone

THE manner of formation of the famous Nubian sandstone has been a matter for controversy for a century. This may be partly attributed to its wide geographical distribution (extending over 30° of longitude and 20° of latitude)[1], its great vertical range (ranging from Palæozoic to Mesozoic), lack of fossils in its greater part, monotony of its lithological characters, and the difficulties entailed in the investigation of almost inaccessible localities in which it outcrops. The problematical unfossiliferous sands and sandstones in representative localities of the Eastern Desert of Egypt and in south-west Arabia were recently examined[2,3], using some of the more recent technique of sedimentary petrology.

Field observations, comprising (*a*) the upward transition from sands to clays to limestones, on a large scale, especially in the Cretaceous Nubian Sandstone; (*b*) the lateral extension and constancy of its sandy beds over large areas and the regular stratification; (*c*) the presence of water-ripple markings with a ripple index of 8·4; (*d*) the presence of a current-bedding similar to that described by McKee[4], with horizontal and inclined laminæ at 26° with the horizontal; (*e*) the presence of bands of transported quartz pebbles of spherical and discoidal shape (their sphericity ranges between 1·00 and 0·57 with 76 per cent of the pebbles having a sphericity which lies between 0·80 and 0·60); and (*f*) the regular surface of contact between the pre-Cambrian and the Nubian Sandstone, indicate that the sandy facies of the Nubian Sandstone of the different ages represent beach and off-shore shallow marine deposits of a sinking peneplained land-mass, excluding the possibility of an æolian origin or their formation under fluviatile, lacustrine, deltaic or estuarine environment.

Mechanical analyses of some eighty samples of the sandy facies showed that the sediments are remarkably uniform and are very well sorted. This sorting suggests either a beach or a dune formation. The histograms given by the Nubian Sandstone, however, are similar to those of modern beach and near-shore shallow-water sands (giving what we may term a 'one-bar' histogram, in which the percentage of the largest fraction is more than 60 per cent and differs from the other percentages by at least 25 per cent, using the Wentworth scale) and are different from those of recent dunes (which may be termed 'two-bar' histograms, in which the difference between the percentages of the largest two fractions does not exceed 25 per cent). This may be taken as a further indication of the marine origin already inferred for the sandy beds.

The mineralogy of some seventy samples from the sandy facies (and of some intercalated clayey and calcareous beds at Khashm-el-Galala, south of Suez) showed that post-depositional dissolution of the minerals was at a minimum (perhaps noteworthy in the light of work in other parts of the world), notwithstanding the old age of the deposit, and the presence of etched grains and certain authigenic minerals. This conclusion is based on the following observations: (1) the presence of the same minerals in the same abundance in the various lithological varieties; (2) the presence of fresh grains of the easily hydrolysed hornblende and augite in the formation; (3) the presence of etched and unetched grains of garnet side by side in the same hand-specimen; (4) the presence of etched staurolite and etched colourless epidotes in the sealed and stabilizing media of the clays and limestones, denoting that the etching is not, in the present case, a criterion of post-depositiona changes. This question of post-depositional change in the Nubian Sandstone is, at present, under detaile investigation.

The mineralogical study showed also that the formation is, in the main, composed of the sam minerals in the same abundance both in a vertica and horizontal sense, which prohibited zoning and thereby correlating the formation on a large scale This lateral uniformity of the mineralogy of the formation in the localities examined points to wind transportation, because such uniformity seems to be a criterion of marine sediments carried by wind[5]. The frosting of most of the quartz grains and their spherical and rounded nature lend evidence for the suggestion; the marine environment previously inferred was not given enough time to polish the grains The detrital minerals have been mostly carried by wind, but they must have been deposited and redistributed under water.

It is, therefore, necessary to abandon the conclusions of Walther[6] and of Fourtau[7], who advocated an æolian (continental) origin for the Nubian Sandstone, a conclusion which gradually crept into some of the general works on stratigraphy[8] and which is held by some of the more recent and leading workers[9,10] on the stratigraphy of the Middle East countries.

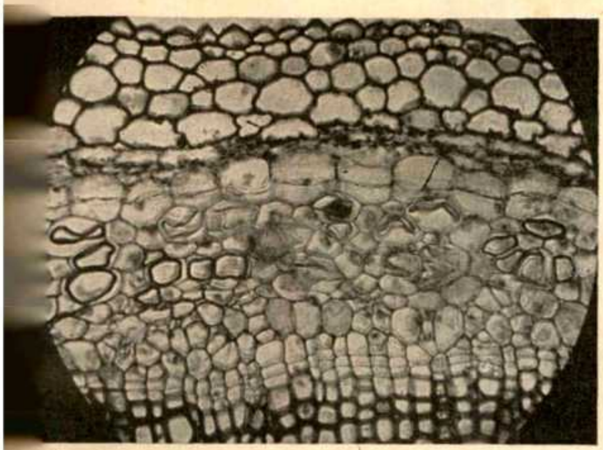
An Endodermal Phellogen in the Stem of *Paederia foetida* Linn.

DURING the course of an anatomical study of *Pæderia fœtida*, a twining shrub of these parts, belonging to the family Rubiaceæ, we found that the phellogen originates in the stem, not in the sub-epidermal layers of the cortex as in most dicotyledons, but in the endodermis. We have seen this in a large number of sections, cut free-hand as well as on the microtome, from various collections of the material made at Dacca. The endodermis itself is a clear and unmistakable layer easily recognized by the presence of the Caspary bands on its radial walls and forming a continuous cylinder enclosing the stelar tissues. After the first tangential division of its cells the inner layer functions as the phellogen, and the outer, together with the whole of the cortex and the epidermis, is sloughed off as cork formation advances. We would like to know if a similar condition has been noticed in any other plant and what may be the causal factors leading to it. This observation is recorded here in the hope that it will attract the attention of other plant anatomists.

We are, of course, aware of instances where the



TRANSVERSE SECTION OF STEM OF *Pæderia fœtida* SHOWING TANGENTIAL DIVISION OF CELLS OF THE ENDODERMIS. (× *c*. 220)

hellogen is formed in the epidermis, cortex or pericycle, as also a couple of cases of interxylary cork ormation and one of cork formation on the endoperm. It is also well known that in *Quercus suber*, he cork oak, the cork cambium first arises in the pidermis, but, due to the frequent strippings of ork, it may later arise in tissues lying considerably leeper, even as far down as the secondary phloem. The case of *Pæderia* is, however, quite different, for here the cork cambium arises at the very outset in the endodermis and is recognizable while the stem is still quite young. The cork which it forms is permanent and there is no deeper-lying phellogen differentiated afterwards unless the stem is wounded.

The accompanying photomicrograph shows the tangential division of the endodermal cells into two layers, of which the inner is to function as the phellogen.

Synthesis of Adenosine Triphosphate by an Enzyme System from Ischæmic Muscle

WHILE investigating the changes in phosphates of muscle in tourniquet shock, Bollman and Flock[1] have confirmed and amplified our previous finding (Green)[2] by showing that the adenosine triphosphate content of rat muscle falls progressively after clamping of the limb to reach a very low level at the time (four hours) at which, when both limbs are involved, fatal shock develops after release. They conclude that "this type of shock is definitely not due to ATP washed out of the muscle because ATP is destroyed during the occlusion and its decomposition products appear to be relatively non-toxic". In our opinion, the results of Bollman and Flock[1] only allow the conclusion that tourniquet shock is not due to a sudden release of adenosine triphosphate into the circulation on removal of the clamp. We never considered it likely that this was the mechanism, since a single dose of adenosine triphosphate injected intravenously produces acute symptoms and not the gradual merging into a shock-like state seen in ischæmic shock and after injection of adenosine triphosphate by routes other than the intravenous[2].

Extensive studies have shown the difficulty of detecting chemically the presence of adenosine triphosphate or its breakdown products in the blood of rats following the injection of lethal doses. Failure to detect it in the blood of rats during ischæmic shock is not therefore proof that it plays no part in the syndrome.

The problem was tackled at another angle. It was postulated[2] that resynthesis of adenosine triphosphate might occur in the limb muscle after release of the clamp, and that it would escape continuously from the damaged muscle cells and leave the limb. Bollman and Flock's conclusion would only be justified if there were evidence of the failure of the enzyme systems of ischæmic muscle to resynthesize adenosine triphosphate. Accordingly we studied the activities of isolated enzyme systems from the normal left- and the ischæmic right-leg muscles of six rats. The findings were precisely similar in each instance.

COMPARISON OF ACTIVITIES OF ENZYME SYSTEMS FROM NORMAL AND ISCHÆMIC RAT MUSCLE.

	Age of enzyme preparation	Normal muscle	Ischæmic muscle
Transmutation : Phosphopyruvic acid P/ml.	2 days 8 days 3 weeks	0·038 0·036 0·031	0·037 0·035 0·032
Resynthesis of adenosine triphosphate P γ/ml.	2 days 8 days 3 weeks	— 0·031 0·012	0·037 0·028 0·013
Deamination : % NH_2–N of added adenylic acid	1 day 2 days	79·9% 80·8%	79·2% 79·7%

A : Transmutation and Resynthesis : Normal muscle and muscle taken from below unreleased clamp after four hours application. Enzyme solutions made up to correspond to 2 gm. of fresh tissue per ml.
B : Deamination : Tissue residue from corresponding preparations *A* treated according to Lohmann and Schuster (ref. 6). Bicarbonate extracts corresponding to 1 gm. of fresh tissue per 3 ml.

As will be seen in the table, the resynthesis of adenosine triphosphate from muscle adenylic acid and phosphoglyceric acid, involving the transmutation of the latter compound into phosphopyruvic acid (Baranowski)[3], as well as the activity of Schmidt's[4] muscle adenylic acid deaminase, were of the same intensity with enzymes prepared from both ischæmic and normal muscle. This strict parallelism held true, not only for fresh, but also for enzyme preparations which had been stored in the refrigerator for different lengths of time.

Since the enzyme systems responsible for the resynthesis of adenosine triphosphate are intact in ischæmic muscle, why, as Bollman and Flock[1] have shown, does the adenosine triphosphate content of the muscle remain at a low level for a considerable time after removal of the clamp ? The reason may be that though the synthesis of adenosine triphosphate will begin once the oxygen supply and ionic concentrations are approaching normal levels, the damaged muscle is unable to store the adenosine triphosphate produced. Such a hypothesis would account not only for the continued low adenosine triphosphate content of the damaged muscle, but also for the slow development of the shock-like state which develops after the release of the tourniquet and which strongly resembles the state following the intramuscular injection of adenosine triphosphate.

Bollman and Flock[1] found that muscle fibres, which have been damaged by vascular occlusion for four hours, take several days to return to normal, and we should not expect the adenosine triphosphate content to reach the normal level before the contractile element of the muscle fibres has been restored (Szent-Györgyi)[5].

These experiments throw no direct light on the role of adenosine triphosphate in ischæmic shock, but they do show that it cannot be ruled out as a possible factor.

Amœbiasis in Durban

IN Durban there is a reversal of the customary incidence of amœbiasis. It is generally stated that an indigenous population is less susceptible to this disease, but in Durban the native African is much more liable than the European or Indian to acute, fulminating amœbic dysentery. In Europeans the condition is usually chronic, with an accent on the vague manifestations. When there is dysentery in Europeans it is usually of the 'walking' type, whereas in Africans the patient is prostrate. Examination of the stool in African cases shows the cytology of an acute bacillary dysentery, without macrophages, but with myriads of large, actively motile, hæmatophagous trophozoites of *E. histolytica*. In fact, as many as 150 parasites have been counted in a single high-power field. The amœbæ are so motile that they are streaked out often with a tail of dragging detritus. The customary distinction between ecto- and endoplasm is not clearly seen in fresh preparations, for the granular material moves into a pseudopod almost as quickly as this is formed, and it is only in older specimens that clear ectoplasm is obvious.

Amœbiasis in Africans has a high morbidity and mortality, for in 1944 there were 1,203 proved cases at King Edward VIII Hospital, with 198 deaths.

Opinions differ as to the reason for this 'racial' susceptibility. The African has been incriminated as the source of amœbiasis here, but rather is it the reverse, for the African is probably meeting a new disease, judging by the severity of the infection.

This manifestation of amœbiasis is probably due to a number of factors: (1) Contact between a susceptible race and a race with a high host-parasite equilibrium. (2) The nature of the African diet, particularly in urban areas and under war-time conditions. This diet is almost exclusively carbohydrate, which is definitely conducive to infection. It may be that there is a sub-clinical intestinal pellagra rendering the bowel wall particularly susceptible to invasion. (3) In rapid passage from individual to individual the amœba gains virulence. (4) The insanitary conditions in which the detribalized native lives around the towns offering employment. The parasite may in part be water-borne, for there is always an exacerbation when the local streams begin to run after the rains. Possible vectors such as flies and cockroaches are numerous, and there can be no doubt that dire transmission takes place. Vegetables as a mediu are not important; for the African under tow conditions gets little of these.

Further work is being done on this problem, an will be reported in due course.

An Illusion of Size

I READ Dr. Loewenstein's letter[1] with the abov title with great interest and began by repeating th tests which he describes. I took a bright nickel three penny piece (1944) and polished it; I took also very dull one which was minted during 1937. placed them on a black background and at once saw as Dr. Loewenstein states, that the older one appeare the larger.

Being somewhat puzzled by this observation, I measured the two coins and this is what I found diameter angle to angle, old coin 3·075 mm., new coin 3·060 mm.; diameter, flat to flat, old coin 3·01 mm., new coin 3·00 mm.; surface, inside raised edges, old coin 2·72 mm., new coin 2·66 mm. Thus in each case the older coin is the larger. These measurements were made with ordinary engineer's gauges. The accuracy was, however, sufficient to establish the fact that the old coin is in certain respects physically larger than the new one. An examination of coins minted in the year 1938, 1939, 1941, 1942 and 1943 indicated that the change in size occurred in between 1939 and 1941. I tried to obtain a coin for 1940 but without success.

Two 1937 coins of the same size were now selected, a dull one and a polished one, and these were placed as before on a black background. With perpendicular lighting the dull one appeared to be either the same size or slightly smaller than the bright one, presumably due to retinal irradiation produced by the latter. With oblique lighting, on the contrary, the dull one sometimes appeared to be slightly larger than the bright one. This seemed to be due to the bright reflexion from the raised edge of the polished coin being somewhat smaller (since the light was reflected from the outside of the raised edge on one side of the coin and from the inside of the raised edge on its other side) than the matt reflexion from the raised edges of the unpolished one. Very careful adjustment of the oblique lighting had to be employed in order to obtain this effect, for otherwise the coins appeared the same size, or the dull one the smaller as with perpendicular lighting.

So far as I can see from these experiments, it is unlikely that the effect described by Dr. Loewenstein is a psychological one. It is either due to an actual difference in size of the two coins or to the way that light is reflected from them. It would be interesting to know if in his experiments Dr. Loewenstein measured the coins to see whether or not they were identical in size.

COLOUR SENSITIVITY OF THE FOVEA CENTRALIS

By E. N. WILLMER
Physiological Laboratory, Cambridge
AND
W. D. WRIGHT
Imperial College, London

AST year, one of us (E. N. W.[1]) demonstrated that a small central area of the fovea was unable discriminate blue-green colours and, in other ways lso, appeared to have the characteristics of the itanopic form of colour-blindness. The observations ere made with small painted test spots suitably xated on the foveal centre. The results aroused onsiderable interest and led to correspondence in Jature[2,3,4,5], in which it was pointed out that König[6], some fifty years ago, had noted that his oveal centre was tritanopic: his observation, how-ver, did not appear to have been generally accepted[7].

A full description of the colour vision of any retinal area requires the measurement of the luminosity curve, the spectral mixture curves and the hue discrimination curve for that area. From data of this type it should be possible to derive information about the spectral sensitivity curves of the retinal receptors and, in the case of the central fovea, to compare these curves with corresponding results for other retinal areas.

The results described below were obtained with the colorimeter previously developed by one of us (W. D. W.[8]) with which colour matching, hue discrimination and luminosity measurements can all be made. The test and comparison fields formed the two halves of a small circular field which, in most of the observations, subtended about 20′ of arc: some measurements were also made with 12′ and 15′ fields. The exit pupil of the apparatus as normally used is about 1 mm. diam., but for most of the final observations the system was modified to permit a larger pupil, about 2 mm. diam., to be used. The observer's head was fixed by a dental impression mouthpiece in such a way as to bring the exit pupil of the apparatus on to the optical axis of the observer's eye. The brightness of the field was of the order of 100 photons, although various brightness levels were used from time to time, and at the violet end of the spectrum the level was necessarily lower.

König's observation that colour matching in the foveal centre could be carried out with only two matching stimuli was confirmed, and Fig. 1 shows the dichromatic coefficient curves for the spectrum for W. D. W., using matching stimuli of wave-lengths 0·65 μ and 0·46 μ. The units of the stimuli were so chosen as to be equal in the match on a yellow at wave-length 0·5825 μ, and the values for the red (r) and blue (b) coefficients in any match were adjusted to bring $r + b = 1$. For the advantages of this type of unit system, reference may be made to previous papers[9,10]. It will be noticed that, with the matching stimuli used, all the spectral colours could be matched by positive mixtures of 0·65 μ and 0·46 μ. At wave-lengths shorter than 0·46 μ, the ratio of red to blue in the mixture increased; this corresponds, in trichromatic vision, to the increase in the amount of red required to match the violet radiations. The increase also means that there are pairs of wave-lengths on either side of some point between 0·45 μ and 0·46 μ (the exact wave-length of the minimum of the red curve, or the maximum of the blue, is difficult to determine) which match each other in colour quality. These matched wave-lengths may be determined by drawing a horizontal line such as AB in Fig. 1 and finding the wave-lengths at which the line intersects the red curve.

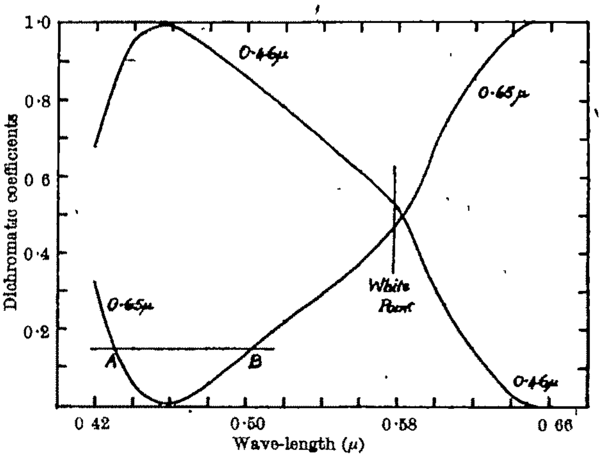

Fig. 1. DICHROMATIC COEFFICIENT CURVES FOR W.D.W. White point at 0 578 μ. A and B, spectral colours which match each other.

The fact that vision is dichromatic implies (see Pitt[10,11], for example) that all stimuli, homogeneous and heterogeneous, can be matched by the appropriate mixture of the two matching stimuli and also, therefore, by some monochromatic radiation. In particular, there is a neutral point in the spectrum at which a white of some defined quality can be matched by the spectral radiation at that point. With a white stimulus having a colour temperature of 4,800° K., the neutral point for the central fovea was located at a wave-length of 0·578 μ. This is a mean value obtained from direct matches between the white stimulus and a radiation from the spectrum, and also from matches between the white and a mixture of the matching stimuli, 0·65 μ and 0·46 μ. Direct observation, supported also by the coefficient curves, indicated a second neutral point in the region of 0·41 μ, but the brightness at which the observations could be made was too low for the point to be determined with certainty.

The luminosity curve was recorded by measuring the energy at wave-length λ required to match a comparison field of constant brightness and quality. The inverse of these energy values plotted against λ then yields what is generally known as the equal-energy luminosity curve. The curve so obtained for the 20′ field is shown in Fig. 2, with a curve for a 2° field drawn for comparison. In making the observations, a red comparison field was generally used to assist foveal fixation. No great difference between the two curves is apparent, although at the short wave-lengths the luminosity values for the smaller field are only about half those for the larger field, while in the region of 0·61 μ a slight hump is revealed. At lower brightness levels, a more pronounced hump has been previously recorded[12] with a 2° field and a small peak with 20′ fields[13].

The coefficient curves can be converted from the unit basis of Fig. 1 to luminosity units by measuring the relative luminosities, L_R and L_B, of the amounts of 0·65 μ and 0·46 μ required to match 0·5825 μ, the wave-length chosen to define the units of the matching

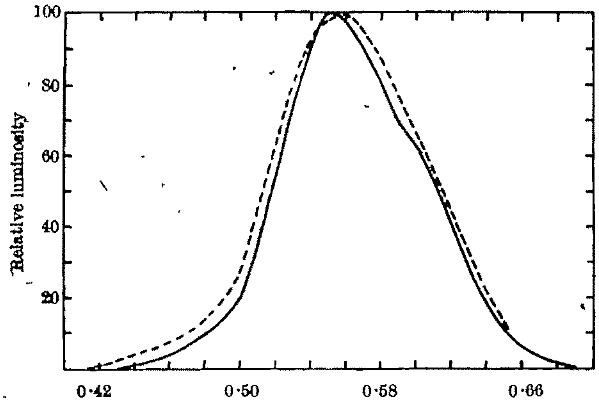

Fig. 2. LUMINOSITY CURVES FOR 20′ AND 2° FIELDS, CENTRALLY FIXATED.
Continuous curve, 20′ field. Broken line, 2° field.

stimuli. A mean value for the ratio L_R/L_B was obtained as 0·73/1·00. If the coefficients, r and b, at any wave-length λ are then multiplied by 0·73 and 1·00 respectively, the relative amounts of 0·65 μ and 0·46 μ, in luminosity units required to match λ, are obtained. The ordinate of the equal-energy luminosity curve at wave-length λ can then be divided into two parts, representing the amounts, in luminosity, of 0·65 μ and 0·46 μ required to match the amount of λ present in the equal-energy spectrum. Repetition of this calculation at intervals through the spectrum then yields the spectral mixture curves shown in Fig. 3.

Since these curves are expressed in terms of matching stimuli which produce all-positive mixture curves, and since, as reported below, 0·65 μ and 0·46 μ are located at points in the spectrum where the change of hue with wave-length effectively vanishes, there is some justification for assuming (though it is not proved) that 0·65 μ and 0·46 μ each stimulate only one of the two receptor units which must exist in the central fovea. If this is so, then the curves in Fig. 3 represent the spectral sensitivities of the two receptor systems responsible for colour perception at the fovea. It should be pointed out, however, that this argument rests on certain assumptions with regard to the nature of the receptors, and further work is necessary before a definite conclusion can be reached. Nevertheless, two features of the curves may be noted: (*a*) the 0·46 μ curve corr sponds quite closely to the 'green' curve given in mo of the derivatives of the fundamental response curv of the Young–Helmholtz theory (for a summary these curves see Walters[14]). This similarity was al reported by Konig[6]. (*b*) The 0·65 μ curve is irregul in shape, but reaches a maximum value at abo 0·60 μ. Because of this irregularity, the curve diffe from the fundamental red response curve as usuall derived; this deviation was again noted by Koni although he gave no indication of the nature of th difference. The maximum near 0·60 μ provides adde support for the existence, under some conditions, the peak in the luminosity curve in that region[1] support which is the more significant because it do not depend upon any very obvious peak in th luminosity curve from which the mixture curv were derived.

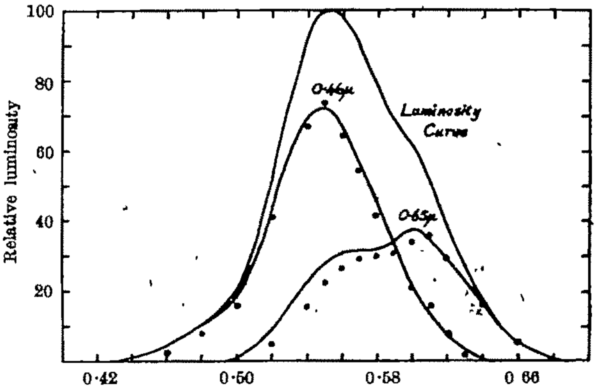

Fig. 3. LUMINOSITY AND SPECTRAL MIXTURE CURVES FOR 20′ FIELD, CENTRALLY FIXATED.
Continuous curves as determined by W.D.W. Circles, spectral mixture curves for E.N.W.

The hue discrimination curve (Fig. 4) was recorde by illuminating one half of the field with mon chromatic light of wave-length λ and the other ha by light of wave-length λ + Δ λ. Δ λ was increase until a difference in hue could just be detected whe the brightness of the two halves of the field wa equalized. The value of the just noticeable wave-length difference Δ λ was then plotted at the wave-length $\lambda + \frac{\Delta\lambda}{2}$ to give the observations recorded in Fig. 4. As will be seen from the individual observations shown in the diagram, the spread of the measurements was considerable. This was probably due to the difficulty in fixating the field correctly, and also to the inherent difficulty of observation with such a small field. The shape of the curve is very different from that for normal vision with a 2° field[15], but it does correspond to the probable discrimination of the tritanope[11], who appears to have reasonably good discrimination in the yellow part of the spectrum, but very poor discrimination in the blue-green. In the neighbourhood of 0·46 μ there is an effective discontinuity in the curve, since the change of hue with wave length falls to zero at this point. Observations in this region have little meaning, since if λ were set at, say, 0·44 μ, then on increasing the wave-length of the comparison field to λ + Δ λ, the quality of the light will tend to become different until λ + Δ λ reaches 0·46 μ, but beyond this point the qualities will tend to approach one another again. With λ at

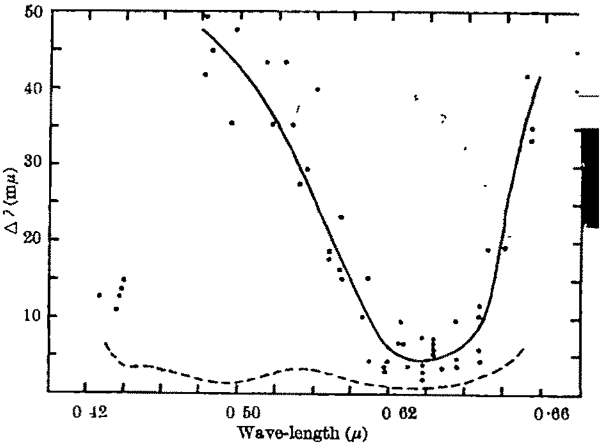

Fig. 4. HUE DISCRIMINATION CURVES.
Continuous curve, for 20′ field. Broken curve, for 2° field.

iorter wave-lengths, for example, $0{\cdot}42\,\mu$, a discriminable step could be observed before $0{\cdot}46\,\mu$ was eached, although the observation was difficult owing o the low intensity.

The results given here represent experimental data hich unequivocally confirm König's original statement that the central fovea is dichromatic and ritanopic. It is difficult to explain why his observations were received with such doubt for so many ears, unless the reason lay in the difficulty of locating he small test field on the fovea and maintaining it n that position for more than a very short time. Vith the test fields used in the present experiments, ny deviation from direct fixation immediately caused breakdown in the matches obtained; whether this vould have been true with still smaller fields it is mpossible to say without further experiment. Prof. I. Hartridge's observations and those of one of us E. N. W.) with painted test fields suggest that it nay not be so. With regard to Prof. Hartridge's onclusions[5] about the dichromatism of retinal areas ther than the central fovea, it is likely that colour natching experiments may confirm this provided the est field is of suitable size, yet we believe that the haracteristics of the central fovea differ significantly rom those of the retinal areas in its immediate neighbourhood. Experiments are in progress to nvestigate this question.

We wish to express our thanks for the continued upport of the Medical Research Council.

ESTER WAX: A NEW EMBEDDING MEDIUM

By Dr. H. F. STEEDMAN

Department of Zoology, University of Glasgow

In view of the many disadvantages of paraffin wax as an embedding medium, a search was made among natural and synthetic fatty acid esters for a more suitable material. No single substance was found which had all the necessary requirements, but a mixture was finally produced using diethylene glycol distearate as the main ingredient. A complete account of this work will be published elsewhere.

A formula suitable for most types of tissue is as follows:

Diethylene glycol distearate	82 gm.
Ethyl cellulose, low viscosity	4 „
Stearin	5 „
Ricinoleic (octadecanediol) diacetate	9 „

The following are among the physical characters of this mixture:

Melting point	48° C.
Section range	4–20 μ at a room temperature of 66° F.
Ribbon range	4–15 μ at a room temperature of 66° F.
Compression after flattening	7·6 per cent at 10 μ.

The diethylene glycol distearate should be heated and filtered before the mixture is made. It should be kept in a molten condition in an oven for two days to allow any free diethylene glycol which it may contain to settle down. The ester may then be decanted.

Ricinoleic diacetate is unobtainable in Great Britain and has to be made from ricinoleic alcohol (octadecanediol) and acetic anhydride. Should these materials be difficult to obtain, castor oil may be used instead.

To make up the mixture put the diacetate into a porcelain pot and add about 15 gm. of the distearate. Heat until the distearate is melted and then add the cellulose. Heat until this is dissolved and then add the rest of the distearate and the stearin. The cellulose dissolves only at a high temperature (approximately 100° C.) and solution should take place with the minimum possible of the two other solids present.

Ester wax is soluble in most alcohols, ethers, esters, ketones, hydrocarbons, chlorinated hydrocarbons and natural oils. The following have been found suitable as clearing agents as well as solvents:

Dioxan.
Ethylene glycol mono ethyl ether ('Cellosolve')
Ethylene glycol mono butyl ether.
Diethylene glycol mono butyl ether.
Cedarwood oil.

As with paraffin wax, a pre-embedding bath of solvent and ester wax is recommended before placing the specimen in ester wax. The time which each specimen requires is the same as when using paraffin wax.

L-pieces are recommended for block-making, and as the block is cooling with the specimen in it the hollow which is produced in the centre due to shrinkage should be filled in with drops of molten ester wax. Rapid cooling of the block by placing it in, but not submerged in, cold water, produces a slightly better block than one cooled at room temperature.

Ester wax is harder than paraffin wax, and in trimming, thinner cuts should be made to prevent chipping. A one-sided razor blade is most suitable.

Sections should be cut at a slower speed than for paraffin wax sections. If cut too slowly poor ribboning results; if cut too fast the sections will crinkle considerably. The crinkles will go when the sections are flattened, but even then the fewer the better. Experience soon indicates the correct speed.

The most important property of ester wax is that of 'ribbon staining'. Instead of flattening on water, as with paraffin wax, ester wax sections may be flattened on stain solutions which easily penetrate the wax and stain the sections. The stain is then drained off, the slide irrigated with water to remove the excess stain, and the sections may then be dried in an oven. To make this clearer the steps are as follows:

1. Flood an albumened slide with methylene blue solution; Loeffler's formula full strength or diluted up to 1 in 10,000. A weak solution is preferable because of the later removal of excess stain which dries on the slide.

2. Lay the ribbon on the stain solution and flatten in by placing the slide on a warm plate or on the surface of warm water at about 40° C. until the wrinkles in the wax disappear.

3. Drain away the excess staining solution. Lower the slide below the surface of distilled water in a petri dish. Gently agitate the slide until it is quite free from methylene blue, and then raise it out of the petri dish with the sections on it. Drain away most but not all of the water. Place the slide in an oven at about 40° C. until dry. *It is important to dry at this temperature or slightly higher or the sections will be wrinkled.* After one hour or even less, the sections will be dry enough for dissolving the wax, differentiating, and counter-staining.

The sections or ribbons may be flattened on water if preferred and treated as paraffin ribbons.

Removal of wax may be done in xylol, which will dissolve the wax without dissolving the methylene blue. It does not dissolve the ethyl cellulose very quickly, however, and a mixed solvent of xylol, ethylene glycol mono ethyl ether ('Cellosolve'), and ethyl acetate is recommended. Should the sections have been stained progressively to a point at which no further extraction of methylene blue is necessary the following mixture is suitable:

'Cellosolve'	10 per cent
Ethyl acetate . ..	45 ,, ,,
Xylol	45 ,, ,,

The wax will be removed in about five minutes and the sections may then be transferred to pure xylol, and mounted with balsam in the usual way.

Generally sections are overstained and differentiated in a mixture similar to the above but with a greater proportion of the stain solvent--'Cellosolve'. In some cases pure 'Cellosolve' alone may be needed to remove the methylene blue from the tissues. Extraction is stopped by placing the slide in the 10 per cent 'Cellosolve' mixture.

Sections can be counter-stained in erythrosin or eosin dissolved to saturation in the following:

'Cellosolve'	20 c.c.
Ethyl acetate	40 ,,
Xylol	40 ,,

This process takes place simultaneously with differentiation of methylene blue or other stain and with the removal of wax. Sections may first of all have part of the wax removed in the 10 per cent 'Cellosolve' mixture, or in pure 'Cellosolve' if heavily overstained with methylene blue, and then may be transferred to the counter-stain. In this the tissue will continue to lose a trace of methylene blue and any remaining wax will be dissolved. When staining is satisfactory the slide is placed in a lower 'Cellosolve' mixture (10 per cent or less). This will prevent any further extraction of methylene blue and will also slightly intensify the erythrosin staining. Finally the slide is transferred to pure xylol, and mounted in balsam.

Clean differentiation of both stains and perfect control throughout all operations are the principal advantages of the method. Other stains may be employed, but methylene blue and erythrosin have, up to the present, been the most satisfactory.

To prevent the methylene blue fading the sections should be mounted in 'Sira' (Stafford Allen & Co., London) and not baked. Such preparations will last for years.

The general outline of the method has been given above. In practice the following solutions are found to cover any combination of wax removal, differentiation of the first stain and application of the counter-stain which may be required:

	1	2	3	4	5	6	7	
'Cellosolve' ..	–	–	5	10	20	40	80	1
E. acetate ..	–	–	47	45	40	30	10	
Xylol .	100	100	48	45	40	30	10	

No. 5 should have erythrosin to saturation.

The following reagents are not usually supplied l the general chemical supply houses, but may obtained from the sources given: diethylene glyc distearate (Messrs. A. Boake Roberts, "Ellerslie Buckhurst Hill, Essex); ricinoleic alcohol (oct decanediol) (Imperial Chemical Industries, Stockto on-Tees); ethyl cellulose, low viscosity (Messrs. J. M Steel, Kern House, Kingsway, London).

THE BRITISH COUNCIL

THE last annual report of the British Counc which covered the year ending March 31, 194 (see *Nature*, 155, 58; 1945), well indicated the in portance of the work of the Council, not only in th war effort but also for the establishment of cultur relations in times of peace. The Council's work i making British contributions to science better know abroad and promoting contacts between British me of science and those of other countries, particularl since the establishment of its Science Departmen four years ago, has become so important that th tenth anniversary of the inauguration of the Britis Council in July 1935 should not be passed unmarke by scientific workers.

The present moment is therefore appropriate t recognize the work of its Science Committee and it Pure Science Panel, of both of which Sir Henry Dale i chairman, as well as its Panels for Medicine, Engineer ing and Agriculture. One of the earliest activities o the department was the publication of a four-pag illustrated newsletter, *Monthly Science News*, in whic accounts of research are presented in a form intelligibl to non-scientific readers. Translated into French, Spanish, Portuguese and Arabic and reprinted in seven different countries, this has now a monthly circulation of 65,000. Compiled in collaboration with learned societies, professional bodies and the scientific and technical Press, *Science Comment*, a monthly compilation of abstracts and reviews started in 1943, is circulated to universities, libraries, etc., and scientific workers overseas to keep them informed of important publications in the scientific and technical field. A section has recently been added dealing with scientific films. The publication is used by booksellers as a valuable indication of British scientific publications likely to be in demand and in introducing technical and scientific periodicals to a wider overseas public.

Much has been done by the Council to enable British men of science to keep in touch with fellow-workers in other countries in the same field; the exchange of papers and specimens has been maintained and an ever-increasing number of requests for scientific information reaches the Council. Much material for *Nature* has been transmitted by the British Council. To facilitate the work in France, a scientific adviser has been appointed to the recently opened office in Paris. Scholarships are awarded by the Council to enable promising students to visit the United Kingdom and learn of British methods; since 1939 more than six hundred students have been brought from the Dominions, Colonies and many other countries.

During the War, some three hundred short-leave courses have been arranged at universities, technical lleges and other institutions in Britain for about n thousand members of the Dominions and U.S. orces, and under the Professional Contacts Scheme large number of scientific and professional men in the ominion and Allied Forces have been put into conct with their opposite numbers in Great Britain d with appropriate professional bodies. The cretary of the Engineering Panel, Prof. S. J. Davies, so acts as consultant to the Council; his section eks to promote a better knowledge of the status d the achievements of British engineering and of the ngineering qualifications granted by British univerties and the major British engineering institutions.

The Medical Department's *British Medical Bulletin* now in its third year, with editions in English, ench, Spanish, Portuguese and Turkish, and its eputation is steadily being extended now that a imited number of copies are available by subcription in Britain; a similar arrangement is being eveloped elsewhere, supplementing the previous striction to medical editors, teachers, investigators nd libraries. On the suggestion of a Swedish prossor of medicine, the English edition is reprinted in tockholm. The present edition exceeds 12,500 copies, nd more than three hundred foreign medical periodials are regularly received in exchange. Requests for copies of papers, bibliographies and general informaon on medical subjects now form an important part f the work, and this and other services have led to many requests for small supplies of new drugs for esearch purposes and for new or improved types of medical instruments and apparatus of British manuacture. The Department also acts as an agent for he supply to foreign laboratories of standard bacterial cultures, sera, etc., and has made a start on a programme of medical films, with commentaries in everal languages, intended primarily for overseas medical audiences.

The chairman of the Medical Panel is Sir Edward Mellanby; of the Engineering Panel, Sir William larke; and of the Agricultural Panel, Dr. J. A. Scott-Watson. Mr. J. G. Crowther is secretary of the Science Committee and director of the Department.

Even without taking account of the general educational work of the Council, there can be no mistaking the value of the contribution of scientific collaboration which the British Council has unobtrusively made during the last ten, and especially the last four, years.

SOME BRITISH WORK ON NUTRITION

NUTRITION is the theme of vol. 2, Nos. 10 and 11 of the *British Medical Bulletin*. The issue opens with an article on nutritional science in medicine by Sir Edward Mellanby. Sir Edward pleads for an international agreement on the optimum composition of bread and other cereal foods which form such a large proportion of the normal diet. The Health Section of the League of Nations has prepared the way for this kind of agreement by working out the international standardization of vitamins and by setting up standards of nutrition in terms of common foods. Discussing bread, Sir Edward says that British men of science consider that it should be made of flour containing as much of the wheat grain as can be physiologically absorbed, that is to say, the whole grain except the outer coarse bran; some North American workers, on the other hand, favour the old type of low-extraction, and white flour with the addition of vitamins known to be present in the wheat grain. The health of the consumer, said Sir Edward, and not the milling or other interests concerned, should control the composition of bread.

This question was raised during a discussion of the nutritional value of bread held by the Nutrition Society last February (see *Brit. Med. J.*, 379, March 17, 1945). The matter was also debated in the House of Lords (see *Lancet*, 320, March 10, 1945; *Brit. Med. J.*, 393, March 17, 1945). During this debate Lord Horder and others strongly criticized the Government's decision last January to use for the national loaf flour of 80 per cent extraction instead of the flour of 85 per cent extraction adopted in 1942. Both the medical journals vigorously discussed this national question in leading articles.

If the composition of bread is vitally important as a basic nutritional factor in health and disease, the importance of other factors is revealed by various expert articles in the issue of the *British Medical Bulletin* under notice. These articles discuss protein metabolism, minerals, nutritional factors in dental disease, the physical, chemical and microbiological determination of vitamins and water metabolism. Dr. S. S. Zilva's article on vitamin C criticizes much of the recent literature about this vitamin. He concludes that so far there is no convincing evidence that vitamin C has an influence on any condition other than scurvy. "It is true," he says, "that synthetic *l*-ascorbic acid has its advantages in certain cases of human disease, but this is by no means balanced by the gross and unwarranted abuse of the compound for nutritional purposes." Dr. Magnus Pyke, of the Ministry of Food, records interesting facts about the problems of British war-time food rationing. The review of selected papers on nutrition which follows the main articles provides a valuable compendium of the most important literature.

This issue of the *British Medical Bulletin* could advantageously be read together with reports (*Brit. Med. J.*, 127, Jan. 27, 1945; *The Lancet*, 829, Dec. 30, 1944) of the Nutrition Society's meeting on the nutritional role of the microflora of the intestines, to some aspects of which the work of the Unit of Animal Physiology working at Cambridge has made valuable contributions (see R. A. McAnnally and R. T. Phillipson, *Biol. Rev.*, 19, 41; 1944). The facts given at this meeting of the Nutrition Society about the biosynthesis of certain vitamins in the bowel will have their influence upon medical practice. *The Lancet* (*loc. cit.*) reviews, for example, the evidence for the view that the use of sulphonamides may sterilize away the beneficent bacteria which synthesize essential vitamins. The conclusion that we shall have to regard the intestinal flora as part of the individual's constitution is yet another of many recent instances of that consideration of the whole organism plus its environment, which is a fundamental concept of modern biology. If, moreover, it is true that certain vitamins may be synthesized in the intestine, it may be necessary, as the *British Medical Journal* (191, Feb. 10, 1945) warns us, to reconsider work done on these vitamins with man as the experimental animal. Certainly the work here discussed by this journal suggests that further investigation is required of the view that diets very deficient in vitamin B may quickly cause physical and mental deterioration.

G. LAPAGE.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Junior Engineering Assistant—The Waterworks Engineer and Manager, Civic Centre, Southampton (August 3).

Assistant Power Station Chemist—The Borough Electrical Engineer, 40–41 Lune Street, Preston, endorsed 'Assistant Chemist' (August 4).

Assistant Agricultural Organizer—The Principal, Agricultural Institute and Experimental Station, Kirton, Boston, Lincs. (August 4).

Head of the Mathematics and Physics Department of the South-East Essex Technical College and School of Art, Longbridge Road, Dagenham—The Chief Education Officer, County Offices, Chelmsford (August 4).

Assistant Lecturer in Physics, and a Lecturer in Metallurgy, in the Bradford Technical College—The Director of Education, Town Hall, Bradford (August 4)

Lecturers (2) in Chemistry—The Secretary, The University, Birmingham, 3 (August 8)

District Mechanical Engineers by the Iraqi State Railways—The Ministry of Labour and National Service, Appointments Department A 9, Room 070, York House, Kingsway, London, W C.2, quoting Ref. No. C.2378.A (August 10).

Engineer and General Manager—The Town Clerk, Town Hall, Upper Street, Islington, London, N.1, endorsed 'Engineer and General Manager' (August 11).

Corporation Chemist and City Analyst to the Corporation of Glasgow—The Town Clerk, City Chambers, Glasgow, endorsed 'Corporation Chemist and City Analyst' (August 11)

Assistant Lecturer in Mathematics at the Bradford Technical College—The Director of Education, Town Hall, Bradford (August 11).

Agricultural Assistant, and an Assistant Dairying Instructress, at the Somerset Farm Institute, Cannington—The Chief Education Officer, County Hall, Taunton (August 11).

Assistant (man or woman) in the Department of Geography—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (August 13)

Lecturers in Chemistry, and a Lecturer in Physics and Mathematics—The Principal, Sir John Cass Technical Institute, Jewry Street, London, E.C 3 (August 15).

Secretary—The Director, School of Oriental and African Studies, University of London, London, W.C.1 (August 15).

Assistant Lecturer in the Department of Mathematics, and an Assistant Lecturer (temporary) in the Department of Physics—The Registrar, University College, Hull (August 18).

Assistant Registrar—The Registrar, University College, Hull (August 18).

Professor of Chemistry—The Secretary, Royal Technical College, Glasgow (August 31).

Lecturer in the Department of Electrical Engineering—The Registrar, The University, Sheffield (August 31)

Lecturer in Applied Mathematics, and an Assistant Lecturer in Applied Mathematics—The Acting Registrar, The University, Leeds, 2 (September 1).

Principal—The Secretary to the Board of Governors, College of Aeronautics, 14 Belgrave Square, London, S.W.1 (September 8).

Lecturer in Geography—The Secretary and Registrar, The University, Bristol (September 10).

Senior Assistant to the Librarian—The Secretary and Treasurer, University College, Dundee (September 30).

Chair of Psychiatry tenable at the Maudsley Hospital—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (October 1).

Principal—The Secretary, King's College of Household and Social Science, c/o University College, Leicester.

Honours Graduates interested in problems of Agricultural and Biological Research—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Practical Engineer to break down Machining Operations from Drawings—The Ministry of Labour and National Service, Appointments Office, 153 Barras Bridge, Newcastle-upon-Tyne, 2 (quoting Ref. No. 211.M).

Teacher of Mathematics and/or Drawing in the Engineering Department of the Burton-upon-Trent Technical Institute and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-upon-Trent (endorsed 'T').

Lecturer (temporary full-time) in Physiology and General Science at the Chelsea College of Physical Education (temporarily evacuated to Borth, Aberystwyth)—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3.

Lecturer (full-time, Graduate) in Electrical Engineering for Electrical Engineering subjects to Higher National Certificate standard, a Lecturer (full-time, Graduate) in Mechanical Engineering for Mechanical Engineering subjects to Higher National Certificate standard, and part-time Lecturers for Evening Classes in Electrical, Mechanical and Production Engineering, Welding, Industrial Administration, Foremanship, Time and Motion Study, Production Control and Industrial Psychology, in the Engineering Department; and a part-time Lecturer in Physics up to General Degree standard, in the Science Department—The Principal, Kingston Technical College, Kingston, Surrey.

CONDITIONS FOR THE PROMOTION OF RESEARCH

THE report entitled "Science: the Endless Frontier" which Dr. Vannevar Bush has presented to the President of the United States and which, it is understood, will be the subject of important legislation in the near future, is of profound interest to scientific workers in Great Britain as well as to those in the United States. The report, a summary of which appears on p. 130 of this issue, owes its inspiration to a request of President Roosevelt last November, and a sentence from his letter is fittingly quoted as striking the keynote of the report: "New frontiers of the mind are before us, and if they are pioneered with the same vision, boldness and drive with which we have waged this war, we can create a fuller and more fruitful employment and a fuller and more fruitful life". The proposals of the report represent in fact a definite attempt to mobilize for peaceful purposes the scientific effort which has proved so effective in war, and to secure that both the range and resources of scientific research are adequate, and the necessary personnel available over a long-term and not merely a short-term period.

Recommendations for the achievement of such objectives could not but fail to attract attention generally, but the most cursory reading of the report reveals how much ground is covered which is common with discussions which have been proceeding in Great Britain during the last few years on the organization and endowment of research. Many of the arguments which Dr. Bush and the distinguished committees on which he called for advice adduce in support of the recommendations of this report are equally valid in regard to the expansion and encouragement of research in Britain, and it is clear from the reports of the four committees that British experience has been in their minds in formulating their findings. The Medical Advisory Committee under Dr. W. T. Palmer, for example, clearly arrived at its recommendation for the establishment of a National Foundation for Medical Research as an independent Federal agency after reviewing the place both of the Medical Research Council and of the University Grants Committee in fostering medical research in Britain.

While the report is undoubtedly inspired by President Roosevelt, much of the ground has clearly been prepared by the surveys previously conducted by the Science Committee of the National Resources Committee on the relation of the Federal Government to research, and by the National Research Council for the National Resources Board on industrial research. Indeed, the findings and somewhat tentative recommendations of the former report published in Washington in 1938 under the title "Research—A National Resource. 1. Relation of the Federal Government to Research" re-appear essentially in those of Dr. Bowman's Committee on Science and the Public Welfare; they have obviously prepared the way for the recommendations for the creation of a National Research Foundation and for strengthening and expanding after the War the research carried on directly by the Federal Government. Dr. Bush's report, however, differs somewhat in scope: the questions arising out of research in social sciences and the humanities are excluded; but on the other hand, the question of medical research is surveyed as already indicated and the place of the universities and colleges is considered, not merely as centres of research but also from the point of view of supplying the trained workers required for an adequate programme of scientific research.

Broadly speaking, it may be said that the strategy of research advocated in this report is to provide the universities and colleges and research institutes with adequate resources for fundamental research, to ensure that the fullest freedom of inquiry is adequately safeguarded, to provide scholarships and fellowships sufficient to ensure the supply of scientific talent required both in fundamental research and in Government service and industry. It is also proposed to extend the organization of research under direct Government control on lines indicated by experience with the Office of Scientific Research and Development to secure support for research in such fields of acute public interest as military problems, agriculture, housing, public health and medicine, which is meagre or intermittent because of lack of interest from private sources or because the demands for capital investment are too high for private provision. There is in fact no suggestion in the report for planning fundamental research. The creation of a single over-all agency for the discharge of Government responsibilities in these fields is intended rather to ensure that no important fields of applied research are neglected, that adequate supplies of trained workers are continuously recruited and that fundamental research is adequately endowed. If those conditions are fulfilled and the free exchange of scientific knowledge fostered, both within and across the national frontier, it is held that there is no risk that the continuous advance of fundamental research will fail to provide the new knowledge upon which depend progress in the war against disease, and the attainment of a higher standard of living.

The emphasis thus placed on free inquiry and on the fullest possible interchange of scientific knowledge is one of the most striking features of Dr. Bush's report. That emphasis is of course to be found in many of the reports on scientific and industrial research which have appeared in Great Britain during recent years; but no other report has yet emphasized so clearly and emphatically the necessity for lifting the existing restrictions on the publication of new scientific knowledge accumulated during the War. Although the report of Dr. Irwin Stewart's Committee on the publication of scientific information is the shortest of the four appended to Dr. Bush's report, it is not the least important, and it has strong claims on the immediate attention of all scientific workers.

During the War, we have been living to a considerable extent on our scientific capital, for men of science who would normally be extending the frontiers of knowledge have instead devoted their efforts to the application of scientific knowledge to the devel ment of new and better equipment, processes materials for war purposes. Many such new scient discoveries as have been made are now classified confidential or secret, and war-time restrictions h prevented the wide dissemination of the kind information upon which science, education a industry normally build. Scientific workers enga on war projects have acquired new knowledge specific fields, but they have not been given acc to similar acquisitions by their colleagues in ot fields.

One of the first tasks which Dr. Bush consid should be undertaken is that of extending the bro base of scientific knowledge available to all scienti workers and lifting, as soon as military conditi permit, even the limited restrictions on publicati of new knowledge in the fields of medical resear which the Secretaries of War and the Navy impos during the first year of the existence of the Office Scientific Research and Development. This, mo over, is not a matter that concerns the United Stat alone. Dr. Stewart's committee points out that so of the information which should be released is p sessed jointly by the United States and its Alli and release in that country should be co-ordinat with release in other countries. The establishme within the National Academy of Sciences of a boa to control the release and prompt publication certain scientific information has previously bee proposed, and such a central agency affords the be means of handling the international aspect also wit the minimum of delay and friction.

This is not the only indication in the report of th importance which is attached by Dr. Bush and th committees he consulted to free and full publicatio as a stimulus to scientific research. Dr. Stewart' Committee urges specifically that, besides adopting liberal policy in permitting the release of scientifi information as soon as it is apparent that it canno be turned against us in the present War, the proposed board, and also Government administrators should encourage investigators to publish the result of their work in fields thus released. Financial suppor for such publication is advocated not only by thi Committee but also by Dr. Bowman's Committee i its recommendations for Government support and sponsorship of international scientific congresses and the like, and for exploring the possibilities of scientific attachés in improving scientific communication. More particularly, after glancing at the question of library aids, Dr. Bowman's Committee refers to the need for Government assistance in dealing with the temporary problem of filling the serious gaps in collections of important European scientific periodicals in American libraries caused by the War, and to the probability that Government assistance will also be required in regard to the abstracting of scientific and technical literature.

Already in December 1940, when the Science Committee of the National Resources Planning Board issued its report on industrial research, the support by scientific societies of the publication of abstracts of the technical literature was becoming increasingly urdensome and inadequate in several branches of cience in face of the rapidly expanding amount of echnical literature published. That report suggested hat an excellent means of Government contribution o industrial research would be proper provision for systematic and complete publication of abstracts of scientific and technical literature. The Bowman Committee makes no fresh recommendations on this matter, but its reference to the existence of this nd of translating and bibliographic problems indicates the importance which American opinion attaches to such matters, and to the thoroughness with which in the post-war years tactical means for the efficient spread and effective utilization of scientific knowledge are likely to be explored and developed in the United States.

As has been indicated, the full success of American policy in this field cannot be achieved in isolation, and that alone would be sufficient reason for singling out this feature of the report for special mention at the moment. However, apart altogether from this question of the removal of war-time restrictions on publication, industry itself in the United States has generally been more disposed to encourage publication than industry in Great Britain. A more enlightened and generous attitude in this respect was strongly urged in the report on industry and research issued in October 1943 by the Industrial Research Committee of the Federation of British Industries, and has been powerfully supported on other occasions by Lord McGowan, Dr. P. Dunsheath and Mr. S. Courtauld. There can be only the warmest welcome for the emphasis on the free and unimpeded exchange of scientific information by publication and in other ways which characterizes this report.

If American strategy in the matter of research, as indicated by this report, appears to be simple, there can be no mistaking the thoroughness with which the correct tactics are being worked out; and the proposals of the report deserve close study by all those concerned with the post-war organization of scientific and industrial research in Great Britain. The report of Mr. H. A. Moe's Committee on the discovery and development of scientific talent, with its long-term plans aimed at ensuring an adequate future supply of engineers and scientific workers by discovering and developing scientific talent in American youth, and its immediate plans to make up in part the deficits resulting from the War, should not be disregarded by those concerned with demobilization and retraining, or with post-war plans in Britain for the expansion and development of the universities and technical colleges. When all allowance is made for the differences in economic and social conditions between the United States and Britain, the factors which determine whether or not a scientific career will attract and hold a sufficient proportion of the ablest minds of each generation are largely independent of geography, and measures or tactics which succeed in one country are likely to be effective elsewhere.

Broadly speaking, the proposals go further towards providing the Government of the United States with a fact-finding and policy-making instrument for science than anything yet set up elsewhere. The suggested National Research Foundation has much wider powers and functions than the central research board proposed last year by the London Chamber of Commerce in its report on "Scientific Industrial Research", and still more than those of the scientific advisers to the Ministry of Production. As a means of co-ordinating policy and developing and applying tactics, it should be a far more effective instrument than the limited powers which in Britain reside in the Lord President of the Privy Council, whether through his responsibilities in regard to the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council or as president of the Scientific Advisory Committee of the War Cabinet. Moreover, there is in Britain at present no means of co-ordinating scientific research on matters appertaining to defence as is provided by the Division of National Defence, and in its absence not only is there risk that long-range research on such matters may not be prosecuted adequately, but in particular that new weapons or forms of warfare which are not clearly the business of any one of the three Services may be neglected. Likewise nothing in the present structure in Britain remotely fulfils the function of the proposed Division of Publications and Scientific Collaboration, despite the work that has already been done by the British Commonwealth Science Committee set up by the Royal Society. Similarly, while some of the functions proposed for the Division of Scientific Personnel and Education might be discharged in Britain by the Appointments Department of the Ministry of Labour if effect were given to the recommendations of Lord Hankey's Committee on Higher Appointments, there is no single body with quite such wide powers or which could exercise the same influence in seeing that no important fields of knowledge are left uncultivated.

While, therefore, little in the proposals or the reports which Dr. Bush has transmitted to the President of the United States has not, so far as relevant to British conditions, found expression in the debate on scientific and industrial research which has proceeded here during the last two years or so, there is considerable difference in emphasis. Moreover, the proposals outlined tend to bring out more clearly some of the weaknesses in the research structure of Great Britain and to indicate measures required, even if those to be applied here are not necessarily those best suited to American conditions. In some respects British organization is clearly ahead of American practice at present, at least so far as Government organization itself is concerned; but the publication of this report, apart from the introduction of any legislation to implement its proposals, should give a marked stimulus everywhere to both thought and action in a field where they are much needed. Not merely is it desirable that we should be ready to co-operate appropriately, where joint action is required, in the removal of restrictions and the fostering of the exchange of information and of personnel. In the field of defence the United Nations Organization will also make it necessary to provide adequate means of co-operation in regard to research on new methods and weapons of warfare and national defence. The war on disease is supremely a task for international co-operation in research, both for treatment and preventive measures. Nor can we neglect to take account of what the United States and other industrial countries are doing to encourage research in industry, if we are to rectify the neglect with which some fields of British industry have been charged in the past, and to attain the industrial efficiency essential for the achievement of our plans and hopes for social security, for full employment and a higher standard of living.

THE RURAL PURSUITS OF PRESIDENT JEFFERSON

Thomas Jefferson's Garden Book, 1766–1824, with Relevant Extracts from his other Writings

Annotated by Prof. Edwin Morris Betts. (Memoirs of the American Philosophical Society, Vol. 22.) Pp. xv+704+36 plates. (Philadelphia: American Philosophical Society, 1944.) 5 dollars.

To most gardeners, I suppose, the name Jefferson suggests that most delicious of dessert plums that was raised by Judge Buel of Albany, New York, the year before Jefferson died. This is a fitting memorial to one who in addition to his activities as ambassador, governor, Secretary of State and President, was both an accomplished naturalist and devoted gardener. Barton, the botanist, who named the genus *Jeffersonia* in Thomas Jefferson's honour, stated "In the various departments of science, but especially in Botany and Zoology, the information of this gentleman is equalled by few persons in the United States".

The "Garden Book", which is the subject of the work under review, begins with an entry for March 30, 1766, a record of the flowering of the purple hyacinth, and ends with the year 1823, but during those fifty-seven years the entries vary greatly in number and extent. During Jefferson's considerable absences abroad no entries occur, and in the total the printed transcriptions of the actual diary occupy only about one hundred of the seven hundred of the present work. The rest of the text is made up of extracts from Jefferson's correspondence, garden entries from other of Jefferson's memoranda and numerous notes. The whole comprises an interesting commentary on the gardening and farming of this period and reflects the personality of an observing and exact mind.

Perhaps the most unusual feature, remembering that the garden book was compiled considerably more than a century ago, is the quantitative character of so many of Thomas Jefferson's notes. Thus he tells us that 2,500 of his early peas filled a pint measure. It required one hundred of his strawberries to fill half a pint, whereas to-day less than twenty would probably be required to occupy the same volume. Again, we read that it took Julius Shard three minutes to fill a two-wheeled barrow and a minute and a half to take it thirty yards. In the same manner he records the amount of water required for mortar and the quantity of vinegar yielded by his grapes. His calendar of the flowering times and the intervals between planting and maturity are similar expressions of a precise mind that was concerned with the efficiency of the mould board of a plough at one period and at another was concerne with the average length of the stride of a horse.

It is obvious from a perusal of these pages th Jefferson had a great love of trees and indeed h wrote that "planting trees has always been m passion inasmuch that I rarely planted a flower my life". Nevertheless, he obviously had an eye f a good herbaceous flower, and the list of plants whic he bought from James Lee of Hammersmith whe he visited England in 1786 included thre specimens of that exquisitely beautiful lily *Liliu canadense*.

Although he was familiar with the renowned garden near Paris, it was the English school of garden desig that aroused his greatest enthusiasm. After his retur from England he wrote "the gardening in that countr is the article in which it surpasses all the earth".

But if gardening was to this distinguished man o affairs his chief hobby, it was equally true that farming was one of his prime occupations. He clearl recognized what is too often forgotten, that horticulture and agriculture are branches of a commo stock that require for their successful developmen to be nourished from diverse fields of knowledge. O agriculture he wrote, "it is a science of the very firs order and counts among its handmaids the mos respectable sciences, such as Chemistry, Natura Philosophy, Mechanics, Mathematics generally, Natural History, Botany".

On his own farm, which covered an area of five thousand acres, more than eleven hundred acres were cultivated and he adopted a seven years rotation with two years of red clover, then crops of vetch and buckwheat, followed by wheat with folded sheep on turnips in the autumn, maize and potatoes, rye and clover. Jefferson evidently believed that the atmosphere was responsible for the restoration of soil fertility, and held that the advantage of manuring is that it will do more in one than the atmosphere would require several years to do. It was his farming activities that led him to devise a mould board that reduced the resistance to ploughing, to experiment with the germination of clover seed on moistened cotton and to determine the value of sowing devices in terms of the amount of seed required which showed that two-thirds of that sown by hand was wasted.

His attempts to introduce rice and olives into South Carolina were but isolated instances, of economic species, among the many endeavours which Jefferson made, often with success, to add to the range of exotic species grown in America.

When we add that he was a pioneer in the development of contour ploughing in the New World and recognized its great value in relation to erosion, it will be obvious that his activities in the rural sciences had a marked influence on their development beyond the limits of his own State. If the pages of this book are something of a patchwork in which the constituent fabrics are of diverse texture and significance, it is equally true that they epitomize the changing fashions and developments of half a century and the colourful occupations of a lifetime. The preparation of the work was made possible by the Penrose Fund of the American Philosophical Society, but it is to the labours of Prof. Edwin Betts that we owe the annotations without which the volume would have lost a great deal of its value, both as shedding light on the preoccupations of a versatile mind and on the horticulture and agriculture of the period.

E. J. SALISBURY.

ANTHROPOLOGY OF PORTUGUESE TIMOR

Timor Português

ontribuições para o seu estudo antropológico. Por Prof. A. A. Mendes Corrêa. (República Portuguesa, Ministério das Colónias: Memórias, Série Antroológica e Etnológica, 1.) Pp. 240+53 plates. Lisboa: Imprensa Nacional, 1944.)

PROF. MENDES CORRÊA gives us an ethnological account of a region about which not very much is known—the Portuguese part of the island of Timor. The greater part of the book is devoted to a study of the racial characteristics of the Timorese, based on unpublished anthropological investigations of Fonseca Cardoso, on a study of natives of Timor brought to the Portuguese Colonial Exhibitions of 1934 and 1940 and on a collection of several hundreds of photographs by a former governor of the colony, Alvaro de Fontoura.

Several writers on Timor have commented on the diversity of physical types among the inhabitants. Prof. Mendes Corrêa makes a classification into four major types which he calls Proto-Malay, Deutero-Malay, Melanesoid and Vedda-Australoid. Except in one region (the Bunak) he finds the Proto-Malay type more or less predominant. He identifies this type with the "Indonesian" type of Deniker.

The author examined the proportions of these four types in different linguistic groups. Our information about the languages of Portuguese Timor was until recently exceedingly scanty and unsatisfactory, and Prof. Mendes Corrêa has not been able to make use of the recent study of this subject by Capell[1]. This study has shown the existence of a number of languages that are quite definitely not Indonesian and not Austronesian (Malayo-Polynesian), but resemble in certain characteristics what are called the Papuan languages. He regards them as "pre-Indonesian". Bunak, mentioned above, is one of them. He also finds that the Indonesian languages of Timor fall into two distinct groups, and those of the eastern part of the island (the Portuguese portion) apparently have closer affinity with the languages of the eastern part of the Indonesian region where it is difficult to draw a line between Indonesian and Melanesian.

The final chapter of the work under review deals with the position of the Indonesians in general and the Timorese in particular in a systematic classification of races, admitting that the available data are not all that could be desired. The author remarks that the current view of the ethnology of the Malay Archipelago is that the existing peoples are the result of a succession of waves of migration from Asia, and suggests an alternative hypothesis by which Timor, and Insulind in general, may have been a region in which an original human stock has been differentiated into divergent types. On this hypothesis, he writes, "we are induced to see in the Proto-Malay of Timor the representative of ancient human stock in evolution. Neither truly Europoid, nor Mongoloid, nor Negroid, nor Veddo-Australoid, but with characters that are common to several stocks well differentiated at present, he appears to us nowadays as a sort of synthetic type, generalized and undifferentiated, of Palaeontology; not as a mosaic, or a crucible for admixtures that are geographically and socially inconceivable in such a remote isolation, but as a 'central type', or rather a truly 'primeval type', of an evolution still at work". "In Insulandia, instead of an area (as has been conjectured) of intense blending of races from the most varied origins, . . . what confronts us is rather, to all appearances, a primeval centre of ethnical differentiation."

In any attempt to judge the evidence for or against this hypothesis suggested by the author, the ethnologist must take into consideration the evidence from linguistics as well as that from physical anthropology. The presence in the mountains of the interior of Timor of peoples speaking non-Indonesian languages, and the existence of a diversity of Indonesian languages some showing affinities with those to the east and others with those to the west, seem to show that there must have been considerable movements of peoples into Timor at some time in the past.

The present work will be welcome to ethnologists and anthropologists as a study of a region about which our information is scanty. There are maps and many photographs. For those who do not read Portuguese easily there is a section in English (pp. 179–215) giving an abstract of the first seven chapters and a full translation of the final chapter.

A. R. RADCLIFFE-BROWN.

MEDICINE AND MANKIND

Medicine and Mankind

By Arnold Sorsby. (Thinker's Library, No. 104.) Pp. xii+116. (London: Watts and Co., Ltd., 1944.) 2*s*. 6*d*. net.

THIS is an abridgement of Prof. Sorsby's fuller work of the same title (Faber and Faber, 1941). More than a hundred years ago it was realized by the pioneer reformers who laid the foundations of British public health that the maintenance of health and the effective treatment of disease were much more than a question of doctor and patient. Man is a social organism and must be studied in relation to his environment. It is more advantageous to the community, for example, that a thousand cases of typhoid fever should be prevented by safeguarding the water supply, or by the detection of a carrier of the typhoid bacillus, than that cases of the declared disease should be treated successfully. The lesson has not been readily learned either by the medical profession or the public. When within the last decade medicine became more scientific and the experimental researches of the laboratory were applied at the bedside, the tendency was to regard the patient as a subject for biochemical investigation rather than an individual with an environment, which frequently enough was responsible for, or favoured, the existence of his malady.

The achievements of preventive medicine, particularly in nutrition, tuberculosis and industrial disease, are inculcating a more comprehensive view, while the foundation of chairs of social medicine at Oxford and Birmingham denotes a further advance in this direction. This aspect of medicine, which regards health and disease as an unstable physicochemical balance constantly responding to changes in the outer world, is well developed in Prof. Sorsby's little book. To this end he employs a wealth of medical examples relating to the genetic, endocrine, nutritional and toxic characters of disease. The book is a little difficult for the non-medical reader, but the author assists him by providing a useful glossary of medical and scientific terms.

A. S. M.

A PLAN FOR RESEARCH IN THE UNITED STATES

THE report of Dr. Vannebar Bush, director of the Office of Scientific Research and Development, to the President of the United States, now published under the title "Science—the Endless Frontier"*, was prepared in response to President Roosevelt's letter of November 17, 1944, asking for recommendations on four specific points. The four questions asked were, first, what could be done, consistent with military security, and with the prior approval of the military authorities, to make known to the world as soon as possible the contributions which have been made during the war effort to scientific knowledge; second, with particular reference to the war against disease, what could be done to organize a future programme of work in medicine and related sciences; third, what could the Government do to aid research activities by public and private organizations; and fourth, could an effective programme be proposed for discovering and developing scientific talent in American youth, so as to ensure the continuance of scientific research on a level comparable to that attained during the War. In his letter of transmittal, Dr. Bush states that he interpreted these questions to relate to the natural sciences, including biology and medicine, and the report includes as appendixes the reports of the distinguished committees on which Dr. Bush called for advice and on the findings of which his own recommendations are based.

The main recommendation for implementing the general finding and conclusion of the report that the Federal Government should accept new responsibilities for promoting scientific research and the development of scientific talent in youth is the creation of a National Research Foundation. The Foundation proposed would be responsible to the President and to Congress, while assuring complete independence and freedom for the nature, scope and methodology of research in the institutions receiving public funds and retaining discretion in the allocation of funds among such institutions. Such responsibility, Dr. Bush urges, is the only means of maintaining the proper relation between science and other aspects of a democratic system, and he considers that a government programme of support for scientific research and education must be based on four further principles: stability of funds over a period of years to enable long-range programmes to be undertaken; the agency administering such funds should consist of citizens selected only on the basis of their interest in, and capacity to promote, the work of the agency; the agency should work through contracts or grants to organizations outside the Federal Government and should not operate laboratories of its own; and support of fundamental research in colleges, universities and research institutes must leave the internal control of policy, personnel, and the method and scope of the research to the institutions themselves.

Accordingly, the Foundation proposed would consist of nine members appointed for, say, four years, and selected by the President in virtue of their interest in and understanding of scientific research and education. They would appoint a chief executive officer as director, and establish initially five divisions, covering medical research, natural sciences, national defence, scientific personnel and education, and publications and scientific collaboration. The function of the Division of National Defence would be t support long-range scientific research on militar matters, leaving to the Services research on th improvement of existing weapons. The Division o Scientific Personnel and Education would be responsible for the support and supervision of the grant o scholarships and fellowships in science, while that fo publications and scientific collaboration would b responsible for encouraging the publication o scientific knowledge and promoting internationa exchange of scientific information. In this field th powers of the Foundation would include the provision of financial aid for international meetings, associations of scientific societies, and scientific research programmes organized on an internationa basis. Emphasizing that the success of the Foundation in promoting scientific research will largely depend on the co-operation of organizations outside the Government, Dr. Bush suggests that while in its grants to, or contracts with, such organizations the public interests must be adequately protected, the organization should be left with adequate freedom and incentive to conduct research. Normally, the public interest would be adequately protected if the Government received a royalty-free licence for government purposes under any patents resulting from work financed by the Foundation. There should be no obligation on the research institution to patent discoveries made as a result of support from the Foundation, and no absolute requirement to assign all rights in such discoveries to the Government. Legislation should leave to the members of the Foundation discretion as to its patent policy, so that patent arrangements could be adjusted as circumstances and the public interest require. Rough estimates given in the report provide for an expenditure of 33,500,000 dollars in the first year, rising to 122,500,000 in the fifth year. Of this total, five millions, rising to twenty, are for medical research, ten each for the Divisions of Natural Science and National Defence, rising to fifty and twenty millions, respectively, and seven millions rising to twenty-nine millions for the Division of Publications and Scientific Collaboration.

In arguing for these recommendations, Dr. Bush points out that without scientific progress the national health would deteriorate, the nation could hope for no improvement in its standard of living, or for increased employment, or indeed maintain its liberties against tyranny. As yet, however, there is no national policy for science, and the Government has only begun to utilize science in the nation's welfare. No government body is charged with formulating or executing such a policy, nor is any standing committee of Congress devoted to the subject. There are areas of science in which the public interest is acute, but which are likely to be cultivated inadequately if left entirely to private support, and we are entering a period when science needs and deserves increased support from Government funds. The colleges, universities and research institutes are the centres of fundamental research and the wellsprings of knowledge and understanding. So long as they are vigorous and healthy, and their scientific workers free to pursue the truth wherever it may lead, new knowledge will flow to those who can apply it to practical problems in government, industry and elsewhere. Many of the lessons learned in the war-time application of science can also be profitably applied in peace, and the rigid controls imposed for security reasons should be removed to restore free-m of inquiry and the healthy competitive scientific rit so necessary for expanding the frontiers of ence. Scientific progress on a broad front results m the interplay of free intellects, working on jects of their own choice as dictated by their own riosity to explore the unknown.

---

* "Science: the Endless Frontier". A Report to the President by Dr. Vannevar Bush. Pp. ix+184. (Washington: G.P.O., 1945.)

Discussing next the war against disease, Dr. Bush ists that striking advances in medicine during the ar have been possible only because of the mass of applied scientific data accumulated through fundantal research in many fields before the War. ogress in combating disease depends on an exnding body of new scientific knowledge, and any tension of medical facilities must be accompanied an expanded programme of medical training and search. The need for broad and fundamental dies is stressed, since progress results from disveries in remote and unexpected fields of medicine d the underlying sciences. Government initiative d support for the development of newly discovered erapeutic materials and methods can also reduce e time required to bring the benefits to the public. ne primary place for medical research is in the edical schools and universities; but the traditional urces of support, largely endowment income, undation grants and private donations, are diminhing. There is no immediate prospect of a change this trend, and research costs have steadily risen. dustry is only to a limited extent a source of funds r fundamental medical research, and to maintain e progress in medicine which has marked the last wenty-five years, the Government should extend nancial support to such research in the medical chools and in the universities, through grants both or research and for fellowships.

Under the heading "Science and the Public Velfare", Dr. Bush emphasizes first the imperative ecessity, from the point of view of national security, of more, and more adequate, military research in eace-time. This is primarily a responsibility of the overnment, and it requires a permanent, independent civilian-controlled organization, having close iaison with the Army and Navy and the clear power o initiate military research which will supplement and strengthen that carried on directly under the control of the Army and Navy. Equally, scientific research is essential to achieve the goal of full employment; a nation which depends on others for its new fundamental scientific knowledge will be slow in its industrial progress and weak in its competitive position in world trade, regardless of its mechanical skill.

From the figures collected by Dr. Isaiah Bowman's Committee on this question, Dr. Bush concludes that expenditure on scientific research by American industry and the Government—almost entirely on applied research—has almost doubled between 1930 and 1940. Whereas in 1930 this expenditure was six times as large as research expenditure of the colleges, universities and research institutes, by 1940 it was almost ten times as large. Moreover, while the research expenditure of the colleges and universities increased by one half during this year, that of the endowed research institutes slowly declined; and accordingly Dr. Bush urges that to enable the colleges, universities and research institutes to meet the rapidly increasing demands of industry and Government for new scientific knowledge, public funds should be used to strengthen their resources for fundamental research. Beyond this, the Government could encourage industrial research by amending the internal revenue code to remove present uncertainties as to the deduction of research and development expenditure as current charges against net income; but while it is also important that the patent system continue to serve the country in the manner intended by the constitution, Dr. Bush recommends that specific action with regard to the patent law should be withheld pending the submission of a report on that subject. Meanwhile, the Government should take an active part in promoting the international flow of scientific information, and in this connexion, in addition to sponsoring international scientific congresses, Dr. Bowman's committee advocated the establishment of international fellowships and, as an experiment, the appointment of scientific attachés serving in selected United States embassies.

Dealing with the means for providing an adequate supply of scientific talent, Dr. Bush believes that the United States has drawn too heavily for nonscientific purposes upon the great natural resources which reside in its trained young men of science and engineers, and that with mounting demands for scientific workers both for teaching and for research, the United States will enter the post-war period with a serious deficit in trained scientific personnel. If ability, and not the circumstance of family fortune, is made to determine who shall receive higher education in science, constantly improving quality should be assured at every level of scientific activity. To meet the immediate deficit the Armed Services should comb their records for men who, prior to or during the War, have given evidence of talent for science, and make prompt arrangements for appointing those who remain in uniform, as soon as militarily possible, to institutions where they can continue their scientific education. They should also see that those who study overseas have the benefit of the latest scientific developments. To encourage and enable a larger number of young men and women of ability to take up science as a career, as well as gradually to reduce the deficit of trained scientific personnel, there should be adequate provision of undergraduate scholarships, graduate fellowships and fellowships for advanced training and fundamental research.

Details of such a programme providing 24,000 undergraduate scholarships and 900 graduate fellowships are worked out in the report of the Committee on the Discovery and Development of Scientific Talent, of which Mr. H. A. Moe was chairman, forming Appendix 3 to Dr. Bush's report. This report covers both long-term and short-term plans, and includes some analysis of the loss of able students to higher education, and data on training of personnel for science and technology.

Finally, Dr. Bush, pointing out that scientific workers have been diverted to a greater extent than is generally appreciated from the search for answers to the fundamental problems on which human welfare and progress depend, urges the necessity of promptly lifting security restrictions to the diffusion of scientific knowledge. In view of the need for co-ordinated policy, he recommends the establishment of a board consisting equally of scientific workers and military men, to decide upon the release of information from military classification and to control the release for publication of scientific information which is now classified. Measures which will encourage and facilitate the preparation and publication of reports should be adopted forthwith by all agencies, government and private, possessing scientific information released from control.

The greater part of the published report is occupied by the four appended reports of the Committees already mentioned. In addition to those of the Moe and the Bowman Committee, these include the report of the Medical Advisory Committee, with Dr. W. W. Palmer as chairman, and the report of the Committee on Publication of Scientific Information, of which Mr. Irvin Stewart was chairman. The longest of these reports is that of Dr. Bowman's Committee, and this report contains a wealth of information of interest to scientific workers. In addition to points already mentioned, it stresses four important changes in existing practices as desirable to increase the effectiveness of research done within the various departments and laboratories of the Federal Government. First, since the most important single factor in scientific and technical work is the quality of personnel employed, establishment of a separate branch of the Civil Service in the United States for scientific and technical positions is recommended. Second, there should be a general up-grading of positions and salaries in the scientific service, with careful selection of new talent; third, appropriations to the principal government scientific departments should be made in lump sums for broad programmes of research extending over several years; and fourth, a permanent science advisory board should be created to consult with government agencies and to advise the executive and legislative branches of government as to the policies and budgets of government agencies engaged in scientific research.

Besides the appreciation of the national research budget, this report gives an analysis of research expenditure in American universities and colleges, and details the more important general principles on which grants to universities should be based: the funds supplied to the universities should be used for the support of significant research with special emphasis on the position of the universities as the chief contributor to pure science; the board allotting the funds should assure itself that the universities have competent and adequately trained personnel to guide the studies; the grants should be made in such a way as to avoid control of the internal policy of the universities, leaving them full responsibility for the administration of the grant after it is once made; and a constant effort should be made to improve the general level of research in institutions of higher education. A further appendix to this Committee's report directs attention to problems of library aids, including inter-library co-operation, abstracting and translating, bibliographic and reference services.

STRUCTURE, DEGENERATION AND REPAIR OF NERVE FIBRES*

By J. Z. YOUNG, F.R.S.

NERVE fibres have become greatly elongated for their function of conduction, but each yet remains essentially a bag, surrounded by a membrane, with the nucleus separated in a special region, the nerve cell body, at one end. It is difficult to obtain a true representation of the immense disproportion between the length and breadth of these cells. The cell body of a mammalian motor fibre is an irregular star-shaped structure about 1/10 mm. in diameter. Attached to this is the axon process which is 1/50 mm. in diameter or less, and yet oft as much as 1 metre in length. Even in the ve shortest peripheral nerve fibres, the axon is 1,0 times as long as it is broad. In very many mot fibres in man the disproportion is 10,000 times. B some of the longest sensory fibres, more than 1 met in length, are less than a tenth of the thickness these motor fibres and the disproportion here mu often approach one million times.

The really astonishing thing is that the cell bod exerts a very immediate influence along this extende fibre attached to it. If a nerve fibre be cut, howev far from the centre, the isolated peripheral portio will begin within a few hours to show differenc from the central part. Ultimately the isolated pa will wither away and disappear, whereas from th central end new processes will be put out. Ho does the nerve cell body produce its control alon such a very narrow thread? Investigation is fo tunately helped by the fact that not all nerve fibre are so very small. Giant nerve fibres are found i some cold-blooded animals, reaching a diameter u to 1/10 mm. in fishes, rather larger in some crustacean and worms. Much the largest nerve fibres of all ar found in the squids, where they range up to 1 mm in diameter and are very suitable objects for analysi and experiment.

Since nerve fibres serve to conduct messages, it i perhaps natural that we should tend to look upo them as wires. The analogy of telegraphic communication is almost too strong to be resisted; but it is in many ways misleading. The inside of a nerve axon is not a rigid structure but a viscou fluid. The large fibres of the squid show this most clearly, for when they are cut across, the content come flowing out from the end. That the substance of a mammalian nerve fibre is also liquid, or at least can be made to flow, is shown by the experiment of crushing it, say with forceps, and then immediately fixing by immersion in alcohol and making suitable microscopic preparations. The material will be found as large masses on either side of the crushed region, from which it has been driven. There is now reason to suppose that not only is the material of the axon liquid, but also that it can flow down the fibre during life. If a mammalian nerve be cut or crushed and the ends examined one hour later, the material of the axons will be symmetrical in the two stumps. But by five hours after the operation the two ends can be distinguished: the axon material reaches more nearly to the cut surface in the central than in the peripheral stump. By the second day the material at the central end is already pouring out into the gap, the central axons becoming reduced in volume. This outpouring suggests that there is a pressure within the fibres which must originate within the cell body. Weiss[1] has recently shown this pressure very clearly by constricting a nerve, which leads to a damming up of the axoplasm central to the constriction. If the cuff is then released the material soon flows forward again. We do not yet know how fast the flow normally proceeds. There may be a continual leak over the surface of the fibre, but the internal movement must be at most very slow, and no doubt the behaviour is very far from that of a true Newtonian liquid.

Although the substance of the nerve fibre can flow, there is considerable regularity of organization of the molecules within it. Evidence of such regularity is seen in the form of 'neurofibrils' in its substance, and also in the birefringence of the axoplasm. The chemist is now becoming more familiar with such tes of crystal-like organization of proteins within quid, for example, in the case of the virus proteins, d it is interesting that there is evidence that a ge part of the proteins which can be extracted m squid nerve fibres shows some resemblance to us and nucleo-proteins. Moreover, in suitable circumstances, axons will contract into spirals, giving ures which recall chromosomes. The nerve fibre, en, like other living tissues, shows a considerable gree of regularity of its component molecules. It possible that this regularity is preserved under the luence of the pressure down the fibre, just as the bstance of some 'dilatant' liquids becomes regularly ranged and solid under stress. It is not surprising at there should be an elaborate arrangement of e molecules which make up the substance of the rve fibre, to ensure the proper ordering of all the ocesses which make it able to conduct, and recharge after it has conducted.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on March 16.

Around the axon of many vertebrate nerve fibres another liquid material, the myelin, with regular mellæ of phosphatide and protein molecules. This not continuous over the whole surface but is broken nto segments by gaps, the nodes of Ranvier. Covering ch segment of myelin is a thin, fenestrated veil of rotoplasm, the cell of Schwann, with a nucleus near e centre of the segment.

These viscous liquid substances which make up the erve fibre are all enclosed in a more rigid tube, the eurilemma. They do not, however, remain in stable quilibrium within it, like liquids filling a tube of lass, but show a distinct tendency to develop an nduloid outline and to break into round or oval rops. This behaviour is characteristic of a cylinder f liquid under surface tension. Since the theoretical work of Thomas Young and of Laplace, and the practical as well as theoretical demonstrations of Plateau, Rayleigh and Darling, it has been known hat a cylinder of liquid remains stable only if its ength is less than its circumference. Plateau showed this by experiments with soap bubbles, and the same phenomenon is seen every day in the drops on a spider's web or the annoying irregularity of a coat of varnish applied to a wire. If the liquid is of high viscosity, the maximum stable length of the cylinder may be increased by many times, but is still finite.

Remarkable unduloid outlines are often seen near the ends of nerve fibres which have been cut and immediately fixed in alcohol. If fibres are teased out in a suitable salt solution, they usually show an unduloid outline along their whole length. Moreover, the waves are related to certain cracks in the myelin known as the incisures of Schmidt-Lantermann, which are always found at the troughs of the waves, as if they were produced by the straining of the lamellæ of the myelin by the stress put upon them in assuming an unduloid outline.

Perhaps even more interesting is the evidence of the operation of surface tension in the degeneration of the peripheral portions of the fibres after a nerve has been cut. In the fibres of rabbits' nerves, the break-up begins to be apparent during the second day after the severance. First the unduloid outline becomes more marked and then the myelin breaks into ovoid segments, shorter than the original segments of Ranvier. The process goes on so slowly that in a nerve taken at a suitable time all stages can be seen. A thin neck is formed at the point of constriction, and when the break finally occurs a small intermediate droplet is often left between the two neighbouring segments. Sometimes still smaller secondary droplets lie on either side of the main one. This is exactly the behaviour seen when droplets divide under surface tension. Darling showed the neck droplets very clearly by photography of the separation of a drop of liquid falling slowly through another liquid of almost equal density.

While this break-up is going on in an isolated piece of nerve, there are probably also many other changes in the physical and chemical properties of the substances concerned. But it seems reasonable to suggest that the primary change which constitutes the degeneration of a nerve fibre is a breaking up under surface tension of the viscous liquid cylinders of axon and myelin into shorter segments and ultimately into spheres. We can then go on to suggest that the cell body normally opposes this tendency of surface tension to break up the fibre by blowing it up from the inside. We have already seen that there is good evidence for the existence of a pressure within the axon, and this may well be the agent which presses the contents against the more rigid tube wall and thus maintains the cylindrical form. If the material of the axoplasm shows dilatancy it is possible that it is normally kept rigid under the pressure and only breaks up when it becomes more liquid after the pressure is removed. The tendency to form an unduloid outline is, however, present all the time, and perhaps manifests itself, even during life, in the formation of the incisures of Schmidt-Lantermann. When a nerve fibre has been severed, the head of pressure is cut off and the surface tension gradually causes the fibre to divide.

At this point the physicist will want to ask all sorts of questions, particularly about the relationship between the surfaces of the myelin and the tube in which it runs. It might seem that if the liquid contents altogether fill the tube there should be no break-up of the cylinder into ovoids, just as the mercury does not, usually, break up in a thermometer. But the tube around a nerve fibre differs from the brass, glass or rubber tubes with which we are familiar in that its wall is permeable to water and salts, and it seems likely that a cylinder of liquid fatty material will not remain stable within such a tube, since water can run in to fill the spaces produced when new surfaces are formed by the unduloid. But we must leave this and many other such questions for the physical chemists, and before we pass to consider the functioning of a nerve merely note that this hypothesis gives the possibility of a very elegant explanation of the genesis of the nodes of Ranvier. If the myelin is a viscous liquid it will tend to form, as it is laid down during development, not a continuous cylinder but very long drops. When an animal is young its myelin segments are short, the initial periodicity being about 150 μ. Though this is certainly very long for a droplet of 3 μ in diameter, it is not impossible if the myelin is a very viscous fluid and enclosed in a tube. Ranvier himself, when he described the nodes, suggested that the myelin is included in the Schwann cell as the drop of fat is in a fat cell. It seems that his analogy may be very near to the truth.

This examination of one aspect of the composition of nerve shows the lines on which one can proceed in trying to give an account of the structure of a nerve fibre. It will be seen that some progress can be made towards a description in terms of the categories of the fundamental sciences. We can begin to know the chemical composition of the parts, substituting moderately exact and general terms such as phosphatide and protein for peculiar ones such as myelin or neurilemma. This is already a great advance, but we can go a little further in indicating how these liquid substances are held in their state, which is not one of equilibrium, by a pressure originating from the nerve cell body. Of course, the physicist will wish for very much more precision in all this, and it is much to be hoped that he will help us to provide it. The histologist can only show the lines along which he believes that it may be sought.

So far we have scarcely touched on the fact that a nerve fibre only remains as it is because it has a function, that is to say, it plays a part in the maintenance of the life of the whole body. Its function is, of course, to conduct messages: from sense organs to centres and back again, thence to muscles. There is much evidence that the message is propagated by the discharge of the previously charged surface of the nerve fibre. A difference of electrical potential, the resting potential, exists between the inside and outside of a fibre, and it has long been suggested following Nernst and Bernstein that this arises as a result of the permeability properties of the surface membrane. If the fibre was permeable to potassium but not to anions, then the former, migrating away from the surface, would form a layer held by the attraction of the residual charge left by their departure. The effect of 'stimulation' is then suggested to be to increase the permeability, allowing a leak which produces a flow of current through neighbouring regions. This current itself stimulates other parts of the surface and so the process propagates.

The inside of nerve fibres, like that of other cells, certainly contains much potassium. By analysis of the contents of single squid nerve fibres, exact estimation has been possible and it has been shown that there is more than thirty times as much potassium inside as out. However, there is considerable evidence that the nerve does not work as a simple diffusion battery. There is still much uncertainty as to the actual potentials involved and as to the permeability to the various ions. Steinbach and Spiegelman[2] have recently shown that the squid fibres are quite freely permeable to sodium, though this does not usually occur within them. It has been shown that during activity potassium does leak out of nerve fibres[3], and application of potassium to the outside of a fibre reduces the resting potential[4]. However, the relationship between potential and the logarithm of the potassium concentration is not always linear as would be expected on the theory, and Shanes[5] suggests that the effect of the potassium may be at least in part to depress the respiratory processes necessary to maintain the potential.

One of the great difficulties of the subject has been that most of the data of nerve physiology have been obtained by the use of bundles of nerve fibres, whereas the verification of the hypothesis evidently requires exact knowledge about the conditions during activity of a single fibre. In the years immediately before 1939, further very direct evidence on the subject was accumulated by the use of the nerve fibres of the crab and especially those of the squid, which are so large that a wire can be inserted inside them. Hodgkin and Huxley[6] and Curtis and Cole[7] have shown that there is, in fact, a large 'resting' potential difference across the surface, which is not seriously interfered with by the presence, even for many hours, inside a fibre, of wire as large as a quarter of its diameter. This certainly suggests that the battery is essentially at the surface. The action potential produced by activity of a limited section of the membrane betw inner and outer electrodes can be recorded and sh to be identical whether the fibre is stimulated at end or the other. However, one of the most expected results has been the demonstration that action potential of a single stretch of membr recorded in this way is diphasic, and not simply abolition of the 'resting' potential. No explanat of this is yet forthcoming.

Other data obtained from these squid-fibres prov further evidence of the changes which occur dur excitation. Thus Curtis and Cole[7] have shown t during the passage of the impulse there is a fall resistance across the membrane, coinciding with peak of the action potential spike. There is thus n very strong evidence of an actual surface cha during excitation. But Cole and his collaborat have gone further yet in studying the electri characteristics of the surface by the application direct and alternating currents across it. They ha revealed that the nerve membrane acts as a rectifi that is to say, presents very different resistance inward and outward current flow. This is not su prising in view of the very marked asymmetry concentration between inside and outside. M unexpected is that there is an element present whi has the electrical characteristics of an inductan that is to say, the potential difference across it proportional to the rate of change of current. V usually associate such effects with magnetic fiel and it is at first a little difficult to accept the idea an inductance in a liquid system such as a ner fibre. But there are several ways in which it can understood as a property of a layer of regular arranged molecules, such as we have every reason think exists at the surface of a nerve fibre.

This work then gives us direct evidence that the are changes at the surface of a nerve fibre at th moment of activity. Other workers have produce equally direct evidence that the electrical curren which flows as a result of this change is actually th agent that stimulates neighbouring points and thu sets up a disturbance which is propagated. Fo tunately, there is already available a large body c evidence about the circumstances in which a electrical current excites a nerve, built up by th labours of many able experimenters from v. Krie and Lucas onwards to the more recent work of A. V Hill and his school[8]. Using this work as a background Hodgkin[9] was able to show that the activity of region of nerve does in fact produce an increase o excitability in front of itself. He did this by coolin or compressing a single nerve fibre of a crab until i just failed to conduct. He tested the excitability o the region beyond the block during the time immediately after the arrival of an impulse at the block, and found that a far smaller electrical impulse than usual was then necessary to excite the fibre. This demonstrates that the transmission along the fibre is by means of these electrical currents flowing in front of the active region. Moreover, Hodgkin also showed that, as would be expected, raising the resistance outside the fibre lowers the rate of conduction, whereas decrease of the resistance increases it.

This abundant evidence makes it very likely that the hypothesis is correct in its general outline, though much remains to be done to make it satisfactory. The degree to which it is successful may be judged by a recent attempt by Offner, Weinberg and Young[10] to produce equations for a circuit equivalent to that of the nerve on these assumptions. The data of Cole and others provide physical measurements for the constants of these equations, and the measure of the completeness of the hypothesis is that these equations predict the conduction velocity of a nerve fibre such as that of a squid with remarkable accuracy. Further, such considerations suggest that the decreased internal resistance provided by increase of diameter of nerve fibres will lead the conduction velocity (c) to grow larger with increased fibre diameter (d), but only slightly, the predicted relationship being $c = kd^{-1/2}$. Pumphrey and Young[11] measured the conduction velocity of a number of squid fibres of various diameters and found approximately this relationship, the data giving $c = kd^{-0 \cdot 6}$ as the best fit. Evidently increase of fibre diameter is a very poor means of obtaining rapid conduction. Indeed the squid with its immense and cumbrous fibres, of a millimetre in diameter, can only reach a conduction velocity of 25 m./sec. This is where the myelin sheath comes in. Nerve fibres covered with a thick layer of myelin conduct much faster than those without it. Thus the earthworm or the prawn obtains a rate approaching that of the squid by the use of fibres of only one tenth of the diameter, but surrounded by myelin layers. Among vertebrates the same method has been further perfected, so that among cold-blooded forms such as the frog rates of 50 m./sec. are obtained with fibres only 20 μ in diameter. For a full understanding of this effect of the myelin we shall have to await further investigation of single medullated fibres, which is only beginning to be technically possible.

From this very brief sketch it will appear that we already know a good deal about the functioning of nerves. We now have a moderately good general theory to describe the method of response and conduction, using the basic categories of physics and chemistry. This is a big step from the special theories from Descartes onwards, which treated of a particular nervous flow. But what we know is scarcely more than enough to stimulate our appetites and remind us of our ignorance. There are many intriguing facts which cannot be fitted into the general picture at all; for example, v. Muralt has recently shown by a most elegant method that a nerve fibre leaks aneurin when it becomes active. Again, for some years it has become increasingly plain from the work of Dale and others[12] that the method by which a nerve message produces an effect in a muscle or other organ at its end is the production of tiny amounts of very active stimulating substances such as acetyl choline. How the production and action of this substance is linked with the conduction of the nerve impulse is a most baffling problem. One cannot help suspecting that the answer will be found in the events which go on in the molecules of the nerve surface.

We have now seen that it is indeed difficult enough to give a general account of the composition, degeneration and function of the nerve fibre. But far worse problems present themselves when we try to describe its history, how it comes to exist in its present state, ready to function. Indeed, no exact treatment of these general embryological and evolutionary problems is yet possible. But we have no right to suppose that it never will be achieved; and it is interesting to make a preliminary attempt to examine the forces by which a nerve fibre is brought to its adult functioning state. One difficulty about exact study of a developing organism is that it is so small that quantitative experiments are hard to perform. This difficulty can partly be overcome in the case of nerve fibres by studying the processes by which they undergo regeneration after injury, for these constitute a kind of development in the adult state. We have seen that after a nerve has been cut across, the axons and myelin break down in the peripheral stump, and are ultimately removed. New axoplasm is put out from the fibres of the central stump and flows back into the tubes left after the degeneration. Along these they may be led back to make connexion with sensory or motor endings similar to their original ones. Thanks largely to the work of Weiss[13], we now understand something of the forces which lead these regenerating streams along suitable surfaces.

Before a new fibre is fully remade, it must acquire the diameter and myelin sheath which it possessed before. We have recently been studying the factors which control the diameter reached by the new fibres. Our first hypothesis was that the size of the parent fibre determines that of the new one, large central making large peripheral fibres, and vice versa. It proved that there is an effect of this sort, and also an influence of the size of the peripheral tube in which the fibres run. But the most powerful factor is one we had not expected to find. New fibres that become connected with the periphery, muscle, gland or sense organs in the skin, become larger than others which fail to become so connected[14]. This means that of the many fibres which enter the degenerated stump, those that make connexion increase, apparently at the expense of the rest. This increase with function should perhaps have been expected. Muscles and glands are well known to show such a functional hypertrophy, but it is a measure of the danger of the analogy of telegraph wires, to which we have already referred, that we had not in fact expected to find that conductors get bigger by functioning. Of course, it is now necessary to analyse the effect much further, and to find out exactly how it is produced, whether by connexion alone or by functioning after connexion. Quite intriguing prospects open if it be true that use increases the volume of nervous tissue. Atrophy of the brain by disuse may be more than a conception of the schoolboy and the comic papers. There is, indeed, already evidence of this. Conversely, exercise and practice may produce skill partly by actually increasing the size, speed and synchrony of conduction in the nerve fibres. However, these are speculations which must be tested in the future.

We see then that a nerve fibre consists of substances the properties of which can be largely defined in physico-chemical terms and which are subject to physico-chemical forces. However, these substances are not in a state of equilibrium, but are maintained in a steady state as part of a complicated system, the organism. The whole elaborate organization of the animal only remains intact because of the functioning of its parts. The special function of a nerve fibre is conduction, and if the nerves conduct wrongly the organization is seriously impaired or actually destroyed. We see this only too clearly in the useless limbs produced by severance or damage to nerves. With no fibres to conduct a sense of pain the fingers are often burned by a cigarette or at the fire. Survival has only been possible because by the processes of development we are given nerve fibres, and all the other organs, with the correct function. This process of development can itself partly be described in terms of physico-chemical forces. We have seen that during nerve regeneration we can discover how the new fibres are formed when the material emerging from the central stump makes contact with the Schwann cells emerging from the peripheral. We can examine quantitatively the forces of pressure and attraction which produce the outgrowth. Again, the size of the new fibres is determined partly by that of the parent fibres, partly by the peripheral tubes into which they enter. But we found that another factor also very much influences the fibre size, namely, whether functional connexion is made or not. Here we see a tendency—not easily referable to ordinary physical and chemical forces—to develop in such a manner as shall be suitable for the preservation of the whole system.

Indeed, this tendency is present, if we look a little closer, behind and in addition to all the physical forces which we have been discussing. The nerve fibres only grow as they do and conduct as they do because during long ages suitable substances for this purpose have been collected together. This has been the work of that same tendency to act in a manner which ensures preservation, assisting the equally fundamental tendency to increase by growth, which is the driving force of evolution. Each type of organism produces more like itself, but not exactly like. What we should perhaps call a tendency to vary also plays a part, by ensuring a continual supply of new types to meet the needs of a changing world.

So we find that we can begin to apply the methods of physics and chemistry in biology, and thereby obtain solutions of our problems which are both more exact and more general than can be reached in biological terms alone. But such methods do not serve to describe all of the phenomena which are presented by the living organism. Unless physicists are prepared to say that their science discovers in all matter tendencies of self-preservation, of increase, of multiplication, and of variation, we must say that these are the special characteristics of living organization, which it has preserved since life first appeared long ago.

OBITUARIES

Dr. P. Pelseneer

PAUL PELSENEER, who died in Brussels on May 5, 1945, was well known to a wide range of scientific men through his connexion with the International Association of Academies and with the International Research Council (now called the International Council of Scientific Unions) which was founded in its place in 1919. But he will be especially remembered by zoologists for his extensive knowledge of molluscs, ranging from embryology to parasitism, and abov all for his anatomical work on this group.

Pelseneer was born in Brussels on June 26, 1863 and graduated at the University of Brussels. He wa a research worker at the laboratories of Naples Villefranche, Roscoff and Wimereux. From 188 until 1918 he held a professorship in the Ghen Teachers' Training College. In 1919 he was appointe permanent secretary of the Royal Academy o Belgium (of which he had been elected a member in 1899), a post he held until almost his last days.

Pelseneer was well known in Britain, and proud o having worked with T. H. Huxley on *Spirula* in 1894 ; their joint work was published as one of the *Challenge* reports, to which Pelseneer had already contributed accounts of the Pteropoda and of the anatomy of deep-water molluscs. The best text-book on Mollusca is that written by Pelseneer for Ray Lankester's "Treatise on Zoology", of which it forms part 5 (1906, translated into English by Gilbert Bourne). He is responsible for the arrangement of bivalves on a primary basis of gill structure, that is now found in most general works on zoology ; it was put forward in 1891, modified in 1906, and his final views are to be found in his report on the anatomy of the *Siboga* lamellibranchs in 1911. In his early studies on the nervous system of gastropods, he showed that orthoneury does not exist in the group Euthyneura, but that the animal has undergone torsion and then untwisted sufficiently to show no chiastoneury. Much of his work is stimulating reading, always clearly expressed, wide in outlook, well illustrated and fresh with new ideas.

One can only refer briefly here to the quantity of work Pelseneer accomplished, which included such divers subjects as the relation of the osphradium to the visceral ganglia, the eyes of bivalves, hermaphroditism, sinistrality, the effect of temperature variation on larvæ, the relative proportion of the sexes, regeneration, hybridism, the chemical composition of the shell, trematode and copepod parasites. His fame rests primarily on his important contributions to morphology, classification, phylogeny and evolution. Late in life he collected into one book, "Essai d'Ethologie zoologique d'après l'étude des mollusques" (662 pages. Brussels, 1935) a concise and monumental survey of almost all that is known of the habits, relations and environment of molluscs, enriched by his own wide research experience. Undoubtedly he ranks as a great zoologist and one of Belgium's greatest scientific workers.

R. WINCKWORTH.

Prof. E. Barclay-Smith

PROF. EDWARD BARCLAY-SMITH, emeritus professor of anatomy in the University of London, died in London on July 5, aged eighty-three. Educated at Brighton College and at Downing College, Cambridge, he graduated M.A. and M.B. in 1890 and M.D. in 1893. Choosing anatomy as a career, he served as demonstrator to Alexander Macalister and was later University lecturer in advanced human anatomy at Cambridge. His faculty for close and accurate observation, his gift of graceful yet forceful exposition, and his remarkably sound and meticulous knowledge of general and topographical human anatomy, established his reputation as a teacher. In 1915 he was appointed professor of anatomy in the University of London, holding the chair at King's ollege until 1927, when, upon retirement, he was reated emeritus professor. He served King's College nd the University of London with selfless devotion, is professional eminence and administrative abilities arning fitting recognition. He became dean of the medical faculty in 1920, a member of King's College ouncil in 1925, and a fellow of that College the same ear: he represented King's College on the committee of management of its associated hospital, acted as chairman of the University of London Board of Studies in Human Anatomy, and was chairman and secretary of the Board of Intermediate Medical Studies. Much appreciated as an external examiner, he served in that capacity the Universities of Cambridge, Durham, Manchester and Birmingham, and was representative of the Royal College of Physicians upon the Conjoint examining board.

A teacher rather than an investigator, Barclay-Smith contributed little to anatomical literature, but ncorporated his wide and exact knowledge in 'Buchanan's Manual of Anatomy", of which he was oint editor. His abiding and scholarly interest in the history of anatomy and anatomical nomenclature was manifested in various little memoirs—gems of erudition—upon classical and neo-classical anatomical terminology.

To the welfare of the Anatomical Society he devoted years of disinterested, unremitting labour, an Argus in its interests and a most gentle Nestor to its younger members. Joining the Society in 1893, he served for many years on its council and on the editorial board of the *Journal of Anatomy*, was joint recorder of *Proceedings* 1925–31, treasurer 1931–37, and secretary 1919–38, declining the honour of the presidency that, as secretary, he might the better serve his fellow members. The Society's travelling fund, designed to encourage and enable junior provincial members to attend the London meetings, was Barclay-Smith's anonymous foundation. Indeed, the Society owes more to him than to any other, and its present flourishing state is perhaps his truest memorial.

Barclay-Smith's personal qualities—in particular his gentle patience, his unassuming bearing, his winsome charm and his genuine concern for the welfare of his fellows—endeared him to a wide circle of friends, colleagues and students, by whom he was beloved, and by whom his memory will be always cherished.

A. J. E. Cave.

NEWS and VIEWS

Engineering at Queen Mary College:

Prof. E. H. Lamb

Prof. Ernest Horace Lamb retires from the chair of civil and mechanical engineering at Queen Mary College, London, at the end of the present session. He has occupied this chair for thirty-two years, having succeeded the late Prof. D. A. Low in 1913. At the time of his appointment, the Engineering Department at East London College (as the College was then called) was rather small and the laboratory equipment meagre and ill-housed. Prof. Lamb set to work at once to develop an engineering laboratory that should be more worthy of the College and of the University. Permission was obtained to extend the laboratory buildings, and a new hydraulic laboratory had already been erected when the War of 1914–18 interrupted the development programme. From September 1914 until April 1919, Prof. Lamb was away from the College on war service, but as soon after his return as possible he continued the work of development. With the help of the late Principal Hatton, he obtained a grant for equipment of £11,000 from the London County Council and also some useful presentation plant, notably a complete boiler and accessories from Babcock and Wilcox, so that by the end of 1923 the laboratories had been rearranged and re-equipped with modern plant for the study of hydraulics, heat engines and strength of materials. He also designed and equipped an instrument-making department which served the science and engineering departments of the College.

The undergraduate school of engineering at Queen Mary College has grown considerably under Prof. Lamb's direction. In addition, much valuable research has been carried out on temperature distribution and thermal stresses in internal combustion engines, propagation of flame in compression ignition engines and on many other investigations. He has always taken a special interest in the application of theory to those elastic and dynamical problems which are so important in high-speed machinery. Prof. Lamb was a member of the University Board of Studies in Civil and Mechanical Engineering and served as its chairman in 1923. He was also a member of the Faculties of Science and Engineering. From November 1924 until November 1928 he was University Dean of the Faculty of Engineering, and thus occupied this important post when the new statutes under the University of London Act, 1926, were being drafted. He was elected a member of the Senate as representative of the Faculty of Engineering in May 1928 and remained a member until 1934, giving most useful service on the Academic Council and many sub-committees of the Senate.

Prof. Edmund Giffen

Dr. Edmund Giffen has been appointed to the chair of civil and mechanical engineering at Queen Mary College, in succession to Prof. E. H. Lamb. Dr. Giffen had a lengthy practical training with Messrs. Harland and Wolff, Belfast, and took his degree in mechanical engineering at the Queen's University, Belfast, later proceeding to M.Sc. He served for thirteen years at King's College, London, first as lecturer and later as reader in mechanical engineering. In this period, he carried out considerable research work, mainly in connexion with injection processes in compression ignition engines, in collaboration with Prof. S. J. Davies, gaining the degrees of Ph.D. and D.Sc.(Eng.) in the University of London. He was active as a member of College and University Boards and served as chairman of the Board of Examiners for the External Engineering Degree. Since 1940, he has been director of research at the Institution of Automobile Engineers' Laboratories, Brentford. During this period, he has been responsible for a great development in the work of these laboratories and has issued important publications, particularly in connexion with the use of gas-producers. In his career he has thus combined experience of practice, of research, of teaching and administration, and his return to university life will be greatly welcomed.

British Agricultural Attaché at Washington and Agricultural Adviser at Ottawa: Mr. A. N. Duckham, O.B.E.

PROF. ROBERT RAE, agricultural attaché on the staff of His Majesty's Ambassador to the United States of America and agricultural adviser to the High Commissioner for the United Kingdom in Canada, will shortly be returning to Britain. He will be succeeded by Mr. A. N. Duckham. Mr. Duckham has been serving as director of the Supply Plans Division of the Ministry of Food, having joined that Department at the beginning of the War. Among his earlier appointments were those of secretary and manager to the Northern Ireland Pigs Marketing Board and research officer to the Bacon Development Board. He has travelled extensively in Europe and North America to examine the economics of animal husbandry. He acted as adviser to the United Kingdom delegation to the Hot Springs Food and Agriculture Conference in 1943 and was a member of the Food and Nutrition Committee of the interim Commission set up by that Conference and also chairman in the United Kingdom of the 1943 Food Consumption Levels Enquiry Committee of the Combined Food Board. Mr. Duckham took Part I of the Natural Sciences Tripos at Cambridge, and holds the Cambridge diploma in agricultural science with distinction in animal husbandry; he is a research medallist of the Royal Agricultural Society. His published work includes reports on agricultural topics and "Animal Industry in the British Empire" which were issued by the Oxford University Press in 1932.

British Iron and Steel Research Association: Dr. C. F. Goodeve, F.R.S.

THE steel industry in Great Britain has recently announced plans for large-scale re-equipment; in addition, it is to establish a central organization for research, to be known as the British Iron and Steel Research Association, which will be under the direction of Dr. C. F. Goodeve, formerly reader in physical chemistry at University College, London, and since 1942 assistant controller for research and development at the Admiralty. Dr. Goodeve has stated that the present intention is for the industry's own research centres to operate in association with teams already working in the universities, as at Sheffield, Cambridge, Swansea, Glasgow, London, Birmingham and Newcastle. The Association will have its headquarters in London, and it will work through a number of divisions and committees, each serving a particular aspect of the steel industry's interests. In this way it is hoped to ensure that problems of the industry reach the research laboratory promptly and that the results of investigations are properly applied. The Research Association will also collaborate with technical bodies studying the raw materials of the industry such as coal and refractories, and will bring together users and makers of steel for the discussion of common problems. It is stated that the industry will contribute up to £250,000 a year to the new Research Association, the total revenue of which is expected to be about £400,000 a year.

National Certificates in Metallurgy

THE Iron and Steel Institute, the Institution of Mining and Metallurgy and the Institute of Metals have joined forces to establish, in co-operation witl the Ministry of Education, a scheme for Ordinary and Higher National Certificates in Metallurgy fo part-time students who are engaged in industry or other pursuits connected with the science o metallurgy. The certificates will be awarded tc students taking approved grouped courses of in struction at certain technical colleges and schools in England and Wales and reaching a certain standard in the final examinations. Examinations will be conducted by the college or school authorities, but syllabuses and examinations based on those of the City and Guilds of London Institute, Department o Technology, or the regional examining unions may, at their discretion, be submitted. The Ordinary National Certificate will be awarded on the results of senior part-time courses, which will usually occupy three years. They will be adapted to the needs of students who have had full-time continuous education up to the age of 15 or 16 or have completed satisfactorily an appropriate part-time course. Senior courses will include adequate provision for chemistry, physics and mathematics; metallurgy will be introduced at appropriate stages and engineering drawing may also be included. The Higher National Certificate will be awarded on the result of advanced part-time courses. These will be suitable for students who have already gained the Ordinary National Certificate or who have reached a corresponding standard and will normally cover at least two years of part-time study. The courses will provide for more intensive study of various branches of metallurgy and will aim at reaching, within the limits of the subjects covered, the standard of university work.

Certificates will be signed by the presidents of the Iron and Steel Institute, the Institution of Mining and Metallurgy, the Institute of Metals and, on behalf of the Minister of Education, by the Principal of the technical college or school at which the award has been gained. Thus the National Certificates will have a professional and national, as well as a local, value. Higher Certificates which record success in specialized foundry subjects will be countersigned by the president of the Institute of British Foundrymen. It is hoped that the possession of a national certificate in metallurgy will foster in the holder a desire to join one or more of the various institutions whose members are concerned with the study, production and use of metals. In the case of those institutions whose membership involves professional qualifications, the holding of a Higher National Certificate will be of assistance in obtaining admission. The formation of a new professional Institution to be known as the "Institution of Metallurgists" and covering all branches of metallurgy is now nearing completion. Membership will be dependent on the production of suitable evidence of qualification as a metallurgist, and it is believed a Higher National Certificate in Metallurgy will be accepted as qualifying the holder in part for the appropriate grade of membership. Further information on the scheme for national certificates in metallurgy can be obtained from the secretaries of the participating institutions or from the principals of technical colleges or schools.

Pharmaceutical Chemistry, Past and Future

MR. H. BRINDLE, chairman of the British Pharmaceutical Conference meeting in London on July 18, gave an address on the origin and development of armaceutical chemistry. He claimed that in days t long past all chemistry was pharmaceutical emistry and all chemists were pharmaceutical emists. Pure chemistry has emerged from it, but day many chemists are drawn irresistibly away m atoms, valencies, electrons, dipole moments, ., to the chemistry of medicinal substances and us back again to pharmaceutical chemistry. The hemists were really neither chemists nor apothe- ries, and they added little to knowledge of chem- ry. The iatro- or medical chemists should be con- lered the first pharmaceutical chemists, for all who actised chemistry at this time were interested in e subject from the medical, that is, the pharma- utical point of view. Their main aim was to pre- re chemical substances for use in medicine, and eir interest in chemistry as a science was distinctly condary. Paracelsus was the first outstanding tro- or pharmaceutical chemist, and he was followed such as van Helmont, Agricola, Glauber, Scheele, unkel, Davy, Berzelius, Liebig, Wohler and Dumas, name a few only who spent periods of their life apothecaries.

The present course of training for the modern harmaceutical chemist includes a fairly com- rehensive study of synthetic drugs. These are creasing very rapidly in number and complexity. hus since the publication of the "British Pharma- opœia" in 1932, seven addenda have been issued, nd in these have been included about fifty entirely ew synthetic organic drugs. These fifty which have een officially recognized constitute only a very mall fraction of the total number which may be onsidered to have been actually introduced in the hirteen years which have elapsed since the "Pharma- opœia" was published. These facts raise great ifficulties in the design of teaching syllabuses in the ubject, for the lecturer has to consider carefully which should be taught and which can be mitted. Enough chemotherapy should be included o fire the students' imagination regarding its possibilities.

However limited his opportunities for carrying it out, any pharmaceutical chemist worthy of the name must have his mind directed towards research. There is a tendency to divide scientific research of all types into the two main classes of pure and industrial or applied research. Pure research is undertaken with no thought of its application. Its results may add to knowledge but it is not carried out primarily for any benefit which it may confer upon any individual, community or even mankind in general. Yet startling results have resulted from pure research; insulin and penicillin, two of the greatest life-savers science has ever produced, emerged almost accidentally during the prosecution of pure research. Pharmacy must be better organized in research activities. The existing research degrees in pharmacy will stimulate research, and now that more pharmacists are graduating in universities, pharmaceutical research is sure to expand. Grants in aid of such research are urgently needed. Some thirty branches of industry have autonomous research associations financed to some extent by the industry concerned but receiving aid from the Government. Although pharmacy may not be so large or so wealthy as these, and may not be able to support a research institution, it could assist by contributions which would be supplemented by government aid. A body for pharmacy similar to the Medical Research Council should be set up.

Conditioning of Plywood

PLYWOOD has so important a future before it that any research which advances its durability is of importance. In Leaflet No. 65 (Utilisation) of the Forest Research Institute, Dehra Dun, India, a description with plan is given of a simple chamber designed by this Institute for the conditioning of finished plywood. It is pointed out that even thoroughly seasoned veneers pick up a certain amount of moisture from glue during the manufacture of plywood; it is necessary that this moisture should be got rid of, before the article is used, by a process termed conditioning. This process ensures the correct drying and setting of the glue, and prevents warping and buckling. Further, some of the softer hardwood timbers, like the Indian semul (*Bombax malabaricum*), and mango (*Mangifera indica*), are liable to blue stain and mould, and even attack by insects if not well conditioned. The drying room is fitted with steam pipes below the floor, and the sheets of plywood are stacked vertically on trolleys above it. There are inlets for the fresh air and outlet chimneys for exhausting the moist air. It is estimated that freshly manufactured plywood requires twenty-four hours for conditioning, and during this period its moisture content will decrease from about 20 to 8 per cent.

Institution of Electrical Engineers: Annual Report

ACCORDING to the report for the year 1944–45 of the Council of the Institution of Electrical Engineers, total membership on March 31, 1945, numbered 26,665, of which 12,573 were corporate members; 2,639 elections to all classes of membership were made during the previous twelve months. During the year, 682 meetings were held in London and at the local centres. There were eleven ordinary meetings, the Radio Section held eighteen meetings, the Measurements Section eight, the Transmission Section seven, the Installations Section eight, and there were six informal meetings. There are ten students sections. Certain revisions of the by-laws have been effected during the year. The Council has set up a permanent Research Committee to advise in matters connected with electrical research. The Institution continues to be active in matters affecting national service, such as War Office correspondence courses, engineering cadetships, the education and training of students and graduates serving with the Forces, etc. A report dealing with "Part-time Further Education at Technical Colleges—including Courses for those returning from the Services" has been issued. Further substantial progress has been made in the work of drafting various codes of practice.

A committee of the Institution has been set up to prepare regulations for the electrical equipment of aircraft, and one is to be formed to deal with radio requirements for civil aircraft. Panels of lecturers are to be formed for the benefit of both young people and adults, and a series of skeleton lecture notes is being prepared for the use of speakers. This scheme is in addition to that already existing whereby senior engineers are enabled to address university engineering societies. An independent Professional Engineers Appointment Bureau has been set up to meet the needs of professional engineers seeking appointments and employers having staff vacancies to be filled. The Council has endowed a chair of electrical engineering at Cambridge for a period of years. Reference is also made in the Report to the Institution library and publications and to the benevolent fund.

Beit Memorial Fellowships for Medical Research

THE Trustees of the Beit Memorial Fellowships for Medical Research refer in their annual report for the year 1944–45 to the death of Lord Onslow, who had served as a trustee since 1928. They also put on record the great loss that not only they, but also the whole of medicine, suffered by the death of Sir Thomas Lewis. Sir Thomas was the first person to be elected to a Beit Fellowship when they were instituted in 1910; and he was a member of the Advisory Board at the time of his death. The Trustees accepted with regret the resignation of Sir Henry Dale and Sir John Ledingham (who has since died) from the Advisory Board; Dr. C. H. Andrewes, Prof. J. H. Gaddum and Prof. H. Himsworth have been elected to fill the vacancies. They noted with pleasure the election this year of Dr. H. D. Kay (fellow 1922–28) and Miss M. Stephenson (fellow 1914 and 1920–22) to the fellowship of the Royal Society.

The following elections were made: *Fourth Year Fellowship (£500 a year)*: Dr. F. W. Landgrebe, to continue the study of the physiology of melanophore hormone and the nutritional factor responsible for the lethal effect of thiourea in rats (Materia Medica Department, Aberdeen). *Junior Fellowships* (£400 a year): Dr. J. F. A. McManus (Canada), to study the topography of lipine distribution in normal and pathological tissues (Department of Zoology and Comparative Anatomy, Oxford); and O. L. Thomas, to study thyroid activity, the pituitary phenomena found experimentally in thyroactivated animals, and the problem of neurosecretion (Anatomy Department, Oxford).

University of Durham: Appointments

MR. G. H. FORSYTH has been appointed to the chair of mechanical and marine engineering at King's College, Newcastle-upon-Tyne. Mr. Forsyth obtained first class honours in mechanical and marine engineering at the University in 1924, and in the following year proceeded to the degree of M.Sc. He was then employed for two years on research work with the North Eastern Marine Engineering Co., Ltd., and after a further period of three years spent at sea, he joined, in 1929, the staff of Lloyd's Register of Shipping, where he has been principal engineer surveyor since 1942. His published works chiefly concern investigations into causes of failure in marine engines.

Dr. David H. Valentine, University demonstrator and curator of the Herbarium and Museum at the Botany School, Cambridge, has been appointed to the readership in botany in the Durham Colleges. He was educated at Manchester Grammar School and St. John's College, Cambridge, where he held an open Major Scholarship in natural science. He took a first class in both parts of the Natural Sciences Tripos in 1932 and 1933, and was afterwards awarded a research grant and a studentship while working on induction phases in photosynthesis. In 1937 he was awarded the degree of Ph.D. for a thesis in plant physiology; and in 1938 he was elected a research fellow of St. John's College. During the War years he has been a temporary officer in the Ministry of Food, on work connected with vegetable dehydration, and visited Africa as the British technical member of the African Dehydration Mission. He has also done work, some of which is already published, on experimental taxonomy, with special reference to the British flora. In 1940 he was president of the Botanical Section and vice-president of the Cambridge Natural History Society.

Anglo-French Conference on Cosmic Rays

AN Anglo-French conference on cosmic rays v be held in the H. H. Wills Physical Laborato University of Bristol, during September 25–27, 19 It is hoped that some ten French delegates w attend, including Prof. P. Auger, Prof. F. Joliot a Prof. I. Curie-Joliot. Physicists in England wishi to attend are requested to send their names to Pr N. F. Mott, H. H. Wills Physical Laboratory, T University, Royal Fort, Bristol, 8. If accommod tion is required in Bristol, early notice should given; every effort will be made to arrange this, b it is hoped that visitors will make their own arrang ments where possible.

Copies of *Nature* for Service Men

LIEUT.-COLONEL J. P. CASTLE, of the Directora of Disposals, c/o British Embassy, Rome, A.P.C C.M.F., asks if a subscriber to *Nature* would be willi to forward him his copy of the journal when he h finished with it. After the headquarters' staff of tl Directorate of Disposals have read the journal, would be passed to the Y.M.C.A., Rome, for distrib tion through the Association's organization to tl troops. We suggest that any reader able to dispos of his copy of *Nature* regularly in this way shoul write direct to Lieut.-Colonel Castle. It may b recalled that the Services Central Book Depot make bulk issues of secondhand magazines; copies hande in to any post office are automatically forwarded t the Depot post free, without any address bein necessary. There are, however, no existing arrangements whereby copies of periodicals can be supplie to individuals through military sources.

Announcements

DR. O. R. GURNEY has been appointed Shillit reader in Assyriology in the University of Oxford a from October 1, 1945, or such later date as he i released from the Forces.

DR. MAURICE STACEY has been given the titl of reader in biological chemistry in respect of the post held by him in the Department of Chemistry, University of Birmingham.

AN offer to establish a trust fund, the capital o which at the end of seven years is expected to b about £10,000, has been received by the University of Cambridge from Mrs. A. M. Sims. The income of the fund would be used to endow a Sims Empire Scholarship for research in physics, chemistry, mathematics, medicine, or any other subject which may be selected from time to time.

ON August 5 the B.B.C. is presenting the first of a new fortnightly series of programmes entitled "Science Magazine". In the first broadcast, listeners will hear an outline of the series as a whole. The programme will be illustrated by excerpts from the recorded opinions of Prof. F. G. Donnan, Sir Robert Watson-Watt, Prof. I. M. Heilbron, Dr. E. Hindle, Sir Howard Florey, Prof. J. D. Bernal, and Dr. C. D. Darlington. This series can be heard on alternate Sundays in the Home Service at 7 p.m.; there will also be a recorded repeat on the following Friday, again in the Home Service, at 4.45 p.m.

ERRATUM.—Dr. D. H. Hey has been appointed to the University chair of chemistry tenable at King's College, London, and not at the Imperial College of Science and Technology as previously announced by the University (see *Nature*, July 28, p. 108).

LETTERS TO THE EDITORS

netration of Fast Nucleons into Heavy Atomic Nuclei

WITH the view of interpreting the disintegration ars' observed in photographic emulsion exposed to smic radiation, Heisenberg[1] developed a theory of e penetration of a fast nucleon into a heavy nucleus, sed on the idealization of nuclear matter as a de-nerate Fermi gas of nucleons, and on the assump-n that the interaction between these constituent rticles and the impinging nucleon can be repres-ted by a simple central potential. As a justification the latter assumption one may adduce the fact at the collision cross-section, computed by Born's ethod of approximation, quite generally tends to ro as the transfer of momentum in the collision creases. The energy distribution of the nucleons ocked out by the impinging fast particle, as given this theory, turns out to depend sensitively on the nge of the central potential, so that a comparison this energy distribution with observation should ad to a fairly accurate determination of this range. ich a comparison has actually been carried out by agge[2] and Ortner[3], under the assumption that the w of force is of the type $e^{-\kappa^2 r^2}$.

The result was very satisfactory, inasmuch as the nge value found in this way coincided, within the mits of empirical errors, with that deduced from e much more precise evidence furnished by proton-roton scattering experiments. The question natur-ly arises, whether the same check would also be uccessful for other laws of nuclear force, for which he range has been determined from the proton-roton scattering data, in particular for potentials of he 'well' and 'meson' types. It is the purpose of his letter to point out that Heisenberg's theory is nfortunately not applicable in its simple form to uclear potentials of those types.

This conclusion cannot be reached merely by nvestigating for such potentials the energy distribu-ion of the ejected nucleons, for one will always get definite answer to this problem for any law of orce. But the inadequacy of the theory becomes pparent when one calculates the mean energy loss f the impinging nucleon per unit of path in nuclear natter. This quantity has also been computed by Heisenberg for the case of the $e^{-\kappa^2 r^2}$ potential; and t is an easy matter, making use of a transformation f variables first proposed by Bagge[2], to extend the alculation to the case of a central nuclear inter-ction of the general form

$$\mathbf{V} = -\,\mathbf{J}.\mathbf{O}.w(\xi) \quad , \quad \xi \equiv \varkappa r, \qquad (1)$$

in which the operator **O** embodies the dependence on pin and isotopic variables and $w(\xi)$ the distance dependence (the parameter $\varkappa$ being a measure of the inverse of the range of force); the function $w(\xi)$ is normalized in such a way as to reduce either to ξ^{-1} or 1 for $\xi \rightarrow 0$, while the normalization of **O** is chosen so that its expectation value be unity in ${}^{13}S$ states of the pair of interacting nucleons: the constant **J** thus gives the 'strength' of the potential for such states. If ε denotes the energy of the impinging nucleon in units of Mc^2 and v the corresponding velocity, one finds for the rate of decrease of ε per unit of path

$$\frac{d\varepsilon}{ds} = -\,\frac{3}{2}\,\overline{\mathbf{O}^2}\,\mathbf{H}\,\frac{1}{\varkappa^2 r_0{}^3}\left(\frac{\mathbf{J}}{Mc^2}\right)^2\left(\frac{c}{v}\right)^2 \qquad (2)$$

In this formula, r_0 denotes the unit nuclear radius (the radius R of the nucleus of mass number A being $R = r_0 A^{1/3}$), $\overline{\mathbf{O}^2}$ is a suitable average of the operator $\mathbf{O}^2$ over spin and isotopic variables of the colliding nucleons (numerically $\simeq 0{\cdot}52$ according to the best data), and **H** is a constant characteristic of the law of nuclear force $w(\xi)$, defined by

$$\mathbf{H} = 2\int_0^\infty u^2\,\mathbf{F}^2(u)\,du, \quad . \quad . \quad . \quad . \quad . \qquad (3).$$

where

$$\mathbf{F}(u) = \frac{1}{u}\int_0^\infty w(\xi)\sin u\xi\;.\;\xi d\xi \qquad (4)$$

is essentially the Fourier integral coefficient of $w(\xi)$. It must be stressed that the same value is obtained for **H** whether one assumes the aforementioned Fermi distribution for the constituent particles of the knocked nucleus or treats these particles as being at rest and entirely independent of each other. This result is in conformity with a general property first enunciated by Williams[4], namely, that the mean energy loss per unit of path of a fast nucleon traversing a nucleus is independent of the mutual interactions and state of motion of the constituent particles of this nucleus.

However, the above formula (2) loses any meaning if the integral **H** does not converge. This eventuality will present itself, as shown by (3), as soon as $\mathbf{F}(u)$ does not decrease faster than u^{-2} for large u. In particular, it is immediately deduced from (4) that for the well type of potential: $w(\xi) = 1$ for $\xi \leqslant 1$, and $w(\xi) = 0$ for $\xi > 1$; and for the meson type $w(\xi) = e^{-\xi}/\xi$, **H** diverges logarithmically. [In the derivation of formula (2), the 'exchange' contribution to the collision cross-section was neglected. It is easily verified, however, that the inclusion of this effect does not prevent the divergence of **H**.] In these instances, the divergence can be traced to the occurrence of an infinite field intensity (either at the boundary of the well or at the centre of the meson field of force), as a result of which the probability for a momentum transfer p, being proportional to $[\mathbf{F}(p/\hbar\varkappa)]^2$, does not decrease sufficiently rapidly for large p.

In view of Williams's theorem, the breakdown of the theory in such cases can, of course, not be ascribed to the use of the Fermi gas model, nor is there any cogent reason to doubt the legitimacy of Born's approximation in calculating the collision cross-section. But the use of a central potential to describe nuclear interaction is no longer justified for momentum transfers $p \gtrsim Mc$: recourse should then be had to a relativistically invariant field theory of this interaction. While such a theory cannot at present be developed in a consistent way, it is possible to surmise its probable effect on the energy distribution of the ejected nucleons. Thus, if one compares the empirical energy distribution with that derived from the theory for a meson potential with a range of force corresponding (by Yukawa's relation) to the mass of the cosmic ray mesons ($\simeq 200$ electron masses), one finds that the theory predicts much too large a proportion of very fast ejected particles: since a more refined theory, using meson field interaction, would (if it is to remove the divergence of **H**) tend to diminish the cross-section for large momentum transfers, it may be expected that it would lead to a better agreement with observation.

A New Interference Effect

IN the course of a class experiment demonstrating the circular Haidinger fringes produced by monochromatic illumination of a thin film between silvered surfaces, it was noticed that coloured circular fringes could be seen if white light illumination was used. The effect is best seen by looking through the film (for example, a thin air film between silvered glass plates, or a thin mica film silvered on both sides) with the eye accommodated for infinity, at a strong point source such as a 'Pointolite'. For normal illumination, the point source is seen surrounded by several rainbow fringes, as in Fig. 1, while for oblique illumination, a sharp circular white-light fringe is seen passing through the source, with concentric rainbows inside and outside, as in Fig. 2. Unlike the usual monochromatic fringes, these fringes are not influenced by lack of accurate parallelism of the silvered surfaces. The sharpness of the white-light fringe improves with increase of the reflexion coefficient of the surfaces; with plates heavily silvered by the Tolansky technique[1], the fringe width is limited only by the size of the source.

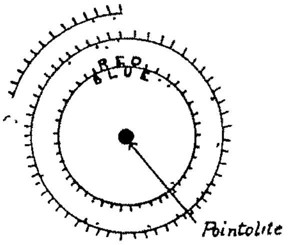

Fig. 1.

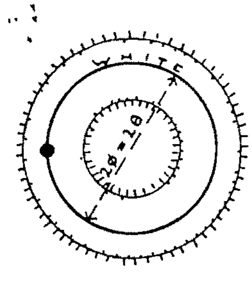

Fig. 2.

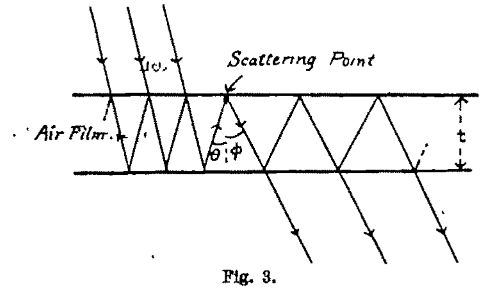

Fig. 3.

A similar effect in reflexion instead of transmission was first described by Newton and explained in detail by Stokes[2], who mentions that he tried unsuccessfully to observe the present effect in light transmitted through an unsilvered glass plate. We suggest the following explanation, similar essentially to that of Stokes. The fact that any illumination at all is visible off the line from the eye to the point source indicates that light is being scattered diffracted from small irregularities in the silve surfaces, and we suppose the fringes to be form by light which has been multiply reflected at angl then scattered, and again multiply reflected at an φ (see Fig. 3). In the first series of multiple reflexio light of wave-lengths for which

$$2t \cos \theta = m\lambda \quad (m \text{ integral}) \quad . \quad .$$

is strongly enhanced in transmission; while af scattering, light of wave-lengths for which

$$2t \cos \varphi = n\lambda \quad (n \text{ integral}) \quad . \quad .$$

is further strongly enhanced. If both (1) and are simultaneously satisfied, then we have

$$2t (\cos \theta - \cos \varphi) = (m - n)\lambda \quad . \quad . \quad .$$

Thus for a given value of θ and for $m = n$, all wav lengths for which (1) is satisfied will appear stron for $\theta = \varphi$, producing the white fringe. For $|m-n$ 1, 2, etc., these same wave-lengths will appear slightly varying angles φ given by (3), producing t various rainbows (each will appear to be practica continuous if m is fairly large). The mechanism in fact, similar to that of the production of whi light fringes by light passed through two thin fil of slightly different thicknesses (sometimes call Brewster fringes), except that in our case the seco path difference is introduced in the same film aft scattering.

It will be seen that the formula accounts quali tively for the facts described, and measurements fringe angular diameters, using an air film abo $40\lambda_{Na}$ thick, have confirmed it quantitatively. Accu ate parallelism is unnecessary since for $\theta =$ $(m - n) = 0$ for all values of t. Some further observ tions confirm this explanation: (*a*) If the silver surfaces are accurately parallel and the 'Pointolit is viewed against a background illuminated by sodiu light, the usual Haidinger sodium fringes may be see superimposed on the white-light fringes. It is the found that for certain values of θ (those satisfying (with $\lambda = \lambda_{Na}$) the system of sodium fringes coincid exactly with the white-light system. (*b*) If th 'Pointolite' is replaced by a point monochromat source (for example, a small aperture in front of sodium vapour lamp, with precautions to avoid a stray light), fringes are seen to appear in the usu positions of Haidinger fringes whenever θ satisfi (1) but are scarcely visible at other angles. (*c*) Clos examination of the white fringe shows that it is mad up mainly of bright spots; this supports the ide that scattering is from discrete irregularities in th silvered surfaces. It is perhaps significant that th silvered plates which best showed the effect had bee exposed to Manchester air for some days, which ma have increased the number of scattering centres this point, however, requires further investigatio

A more detailed treatment enables calculation o the intensity distribution in the white-light fring and explains the sharpening of the fringe with in crease of the reflexion coefficient of the silvered sur faces, just as in the case of monochromatic Haidinge fringes.

Scaliness of Wool Fibres

According to a theory of milling which was developed some years ago, fabrics are capable of undergoing milling shrinkage only when some or all of the component fibres possess a surface scale structure, are easily deformed, and show perfect recovery from deformation[1]. It should, therefore, be possible to make wool unshrinkable by modifying its elastic properties instead of by the customary method of attacking the surface-scale structure. The truth of this deduction has been established in a number of ways[2,3,4]. Perhaps the most convincing is the recent demonstration that woollen flannel can be made unshrinkable by treatment with mercuric acetate or benzoquinone[4]. Both reagents increase the resistance of the fibres to deformation; both *increase* the scaliness of the fibres, as measured in soap solution by means of the lepidometer[5,6]. In the light of these results it was concluded that mercuric acetate and benzoquinone make wool unshrinkable by modifying the elastic properties of the fibres, and not by attacking or masking the surface-scale structure.

The scaliness measurements, on which the validity of the preceding conclusion depends, were carried out under conditions which reproduce the fibre-travel responsible for milling shrinkage: single fibres were suspended, root end downwards, from a tension-measuring device and rubbed longitudinally in soap solution between the rubber surfaces of the lepidometer. The maximum tension developed by the creeping fibre was taken as a measure of its scaliness. Precisely similar results are obtained when the scaliness of fibres treated with mercuric acetate or benzoquinone is measured by the older 'violin bow' method[7], which is, however, less satisfactory in being less closely related to milling conditions. It consists simply in determining the angle of tilt necessary to cause a 'bow' of fifty fibres to slide on a face cloth, first in the direction of the root end (θ_1) and then in the direction of the tip (θ_2), the scaliness (S) being defined as:

$$S = \frac{\tan \theta_2 - \tan \theta_1}{\tan \theta_1} \cdot 100.$$

The results obtained by this procedure are given below:

Treatment	Percentage shrinkage in area of fabric in milling	Scaliness of fibres in:	
		Air	Sodium oleate solution (0·2%)
Untreated	37·3	32·6	142
Mercuric acetate	4·4	31·2	182
Benzoquinone	20·2	31·4	>200

Thus, whether the scaliness is measured under static or dynamic conditions, whether it is measured on wool or rubber surfaces, the results indicate that the unshrinkability of fabric treated with mercuric acetate or benzoquinone is not due to reduced scaliness of the fibres.

The preceding results, like those given by the lepidometer, are in sharp contrast with those recently obtained by Bohm[8], and the most probable cause of the discrepancy is his use of a hard, inflexible surface —glass—for the friction measurements. Although Bohm's data are therefore of doubtful value in relation to the milling process, some explanation must be offered for his observation that the two coefficients of friction (towards the root and towards the tip) of fibres treated with mercuric acetate or benzoquinone are so nearly alike, whereas those of untreated fibres are far apart. A possible explanation is to be found in terms of Rudall's model[9], which was originally devised to explain why untreated fibres migrate when they are rubbed longitudinally between wet glass plates. A wooden ratchet was provided with rubber 'scales' as shown in the sketch. When the model was pushed towards the 'root' end on glass, the friction was less than when it was moved in the direction of the 'tip', owing to the different configurations adopted by the edges of the 'scales', as shown in (*a*) and (*b*), respectively. It is obvious that no such difference would arise on glass plates if the rubber were replaced by a more rigid material. Since cross-linking reactions increase the resistance of wool fibres to deformation, the differential frictional effect will be correspondingly reduced on glass, if the scales of the fibres behave in the same way as the 'scales' of the model. As has already been shown, however, the difference in friction would still be observable on flexible surfaces, and it seems likely that Bohm's observations are a measure of the effect of mercuric acetate and benzoquinone in modifying the elastic properties of the fibres.

Mechanism of the Feulgen Reaction

The Schiff reaction for aldehydes using the addition compound of sulphurous acid with fuchsine was applied by Feulgen for his well-known reaction for the localization of desoxyribosenucleic acid in cells. The specificity of this localization in the reaction has recently been questioned[1], and led to the series of investigations to be described, from which it is concluded that the reaction is essentially one of adsorption, and that nucleic acid is not necessarily concerned in the reaction. Normal, malignant and embryonic tissues of mouse, fowl and normal rabbit tissues, fixed by various methods, were used in the staining tests.

(1) *Colour of the stain.* It can readily be shown that though neutral fuchsine stains filter paper or sections bright red, the typical mauve colour is produced if the dye is used in weakly acid solution, as in the usual Feulgen method. Though the colour is washed out of filter paper by sulphur dioxide water, it is not removed completely from other materials such as newsprint, poor quality cotton wool, or alumina. Furthermore, a section stained bright red by neutral dye will show the typical Feulgen colour if dipped

into acid buffer solution. The colour does not therefore indicate anything about the nature of the material.

(2) *Hydrolysis.* In the Feulgen reaction the tissue is placed in $N/1$ hydrochloric acid for a few moments 'to hydrolyse the nucleic acid'. But acid is known to destroy much of the cytoplasm[2], though the nucleus remains intact for a longer time in the same circumstances. The method is, in fact, used to prepare free nuclei for analysis. An examination of finely minced tissues subjected to such treatment for varying intervals will leave no doubt that very extensive destruction of the cytoplasm occurs during hydrolysis, and will suggest that the localization of the stain in the nucleus in the Feulgen reaction may well be due to the fact that only a ghost of the cytoplasm is left after hydrolysis. Before hydrolysis both the cytoplasm and nucleus of a section stain mauve with acidified fuchsine, but after hydrolysis only the nucleus takes the stain; the appearance is then exactly the same as that of a normal Feulgen stain for such tissue.

(3) *Staining of chromosomes.* The Schiff reaction is carried out in solution. When a solid phase is present, as in the Feulgen reaction, complications due to adsorption may occur. If an adsorbing material is present which will disrupt the sulphurous acid–fuchsine compound by having a stronger attraction for the dye than the sulphurous acid, the mauve colour will reappear. This can be shown in a test-tube reaction by adding alumina to Schiff reagent, when the dye (in the coloured form) is adsorbed on the solid, even in the presence of a large excess of sulphur dioxide. As it is well known that chromosomes will adsorb and concentrate dye from a weak solution, this effect cannot be disregarded in the Feulgen reaction. In fact, the varying distribution of the Feulgen stain in chromosomes with heterochromatic regions is equally well shown by certain simple stains such as crystal violet, where only differential adsorption need be considered.

The degree to which adsorption acts in the Feulgen reaction can be found by adding a large excess of sulphur dioxide to the Feulgen stain, and staining as usual. Thus in one experiment there was more than forty times the wet weight of the section of sulphur dioxide in excess; even if the section were all nucleic acid, there was not enough to act with the sulphur dioxide present to liberate any colour. Nevertheless, a perfectly normal 'Feulgen reaction' was obtained. Similarly, if the section is pretreated with sulphur dioxide water before immersing in the stain, this sulphur dioxide will react with all the desoxyribose, and thus no further reaction can be expected when the section is placed in the decolorized fuchsine solution. In spite of the fact that no dye can thus be liberated by chemical reaction, here again a perfectly normal 'Feulgen reaction' results.

It seems clear, therefore, that neither the presence nor the location of the stain bears any relation to the presence or absence of either of the two nucleic acids, but can be merely a reflexion of the adsorbing power of the chromosomes. It should be noted that the adsorbing reactivity is only developed after hydrolysis. This different adsorbing power, with which is associated differences in the biological activities of the parts of the chromosomes, cannot therefore be proved to be due to differences in nucleic acid concentrations or different varieties of nucleic acid (ribose or desoxyribose types) by the use of the Feulgen reaction. For the demonstration of these adsorption differences in the chromosomes the use of acidified fuchsine on acid-digested material is more convenient than the complications of the Feulgen reaction using decolorized fuchsine.

All expenses in connexion with this work were borne by the British Empire Cancer Campaign.

Viridin: a Highly Fungistatic Substance Produced by *Trichoderma viride*

The mould *Trichoderma viride* Pers. ex Fries is generally known to possess marked powers of antagonism to other fungi. It has been previously shown[1] that some strains of this mould produce gliotoxin. We have recently found a number of strains which produce another substance, which we propose to name 'viridin', characterized by remarkably high fungistatic activity.

Our viridin-producing strains of *T. viride* are characterized by the rapid production of a bright yellow colour in the culture medium, particularly in media containing nitrate, such as Czapek-Dox. In our experience, gliotoxin-producing strains of *T. viride* do not produce this pigment. We have found that if suitable pigmented strains are grown on thin layers of Weindling[2] or Raulin-Thom medium, for four to six days at 25° C., the culture medium develops high fungistatic activity and may be diluted 2,000 times or more and still inhibit the germination of conidia of *Botrytis allii* Munn. The active material (viridin) has been isolated from such culture filtrates by extraction with chloroform, evaporation to dryness under reduced pressure, followed by crystallization from ethyl alcohol.

The viridin thus produced appears as colourless rod-like prisms, which decompose without melting at 217–223° C.; yields of the order of 45 mgm. per litre of culture filtrate have been obtained. The crystals contain no nitrogen, sulphur or halogens and give no ash on combustion. Analyses are given in Table 1.

Table 1.

%	Found	$C_{20}H_{16}O_6$ requires
C	68·3	68·2
H	4·7	4·6
OCH_3	8·9	8·8 (for one OCH_3)
Active H (Zerewitinoff)	0·5	0·6 (for two H)
CH_3 attached to C	3·5	4·3 (for one CH_3)
Molecular weight (depression of f.p. of bromoform)	331	352·2

Viridin is almost insoluble in ether and camphor and gives no coloration with alcoholic ferric chloride. It is optically active; for a 1 per cent solution in chloroform, $[\alpha]_D^{18}$ is $-$ 222°.

The addition of phloroglucinol and hydrochloric acid to a very dilute alcoholic solution of viridin gives a deep reddish-violet colour. This colour resembles that given by lignin with this reagent, and indeed we were prompted to try this reaction by a similarity between the properties of lignin and a substance tained from viridin by reduction. By means of is test with phloroglucinol and hydrochloric acid, ridin may be distinguished from gliotoxin, which ves no colour.

TABLE 2.

Substance	Least concentration (μgm./ml.) preventing germination of *Botrytis allii* conidia
Viridin	0·005
Gliotoxin	3·0
Mercuric chloride	0·5
Di(ethylmercuri) hydrogen phosphate	0·025

Aqueous solutions of viridin at *p*H 3·5 prevent the rmination of *B. allii* conidia at concentrations of e order of 0·005 μgm./ml. Results of a comparison ith several known fungicides are given in Table 2. his high sensitivity to viridin is not confined to . *allii*; *Fusarium* spp., *Trichothecium roseum* and *ephalosporium* spp. have shown the same order of nsitivity, but a number of species of *Penicillium* nd *Aspergillus* require concentrations of 3–6 μgm./ml. prevent germination. iridin does not appear be markedly bacterioatic.

Aqueous solutions of virlin are unstable, except t low *p*H. At *p*H 6·5, the ctivity of a 100 μgm./ml. olution is almost comletely lost in one day, t *p*H 7·5 activity is lost nstantaneously, but soluions at *p*H 3·5 are relaively stable. Gliotoxin hows a similar intolernce of high *p*H, but is ore stable than viridin.

Some progress has been made towards the elucidation of the constitution f viridin. Work on its chemical and biological roperties is being continued and our results will e reported in greater detail elsewhere.

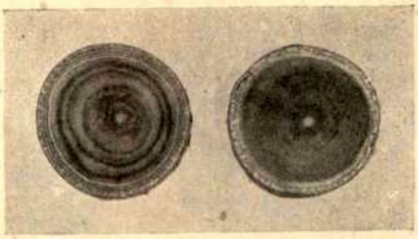
Abnormal Lignification in the Wood of some Apple Trees

FOR some years past, a condition generally referred to as 'rubbery wood' has been observed in many Lord Lambourne apple trees. A characteristic feature of this 'rubbery wood' is the flexibility of the affected shoots and branches, which allows them to be bent much farther than normal shoots before breaking, just as if they were composed of rubbery material. The affected branches usually taper very rapidly from base to tip. The cause of the trouble has not yet been established, but suggestions as to its origin have been put forward by several workers[1,2,3].



(*a*) (*b*)
Fig. 1. MILLER'S SEEDLING. TRANSVERSE SECTIONS OF (*a*) NORMAL BRANCH; (*b*) 'RUBBERY' BRANCH. NAT. SIZE.

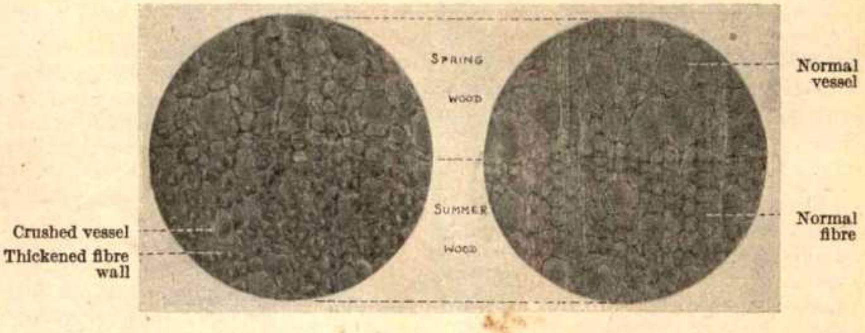


Fig. 2. LORD LAMBOURNE. STRUCTURE OF (*a*) 'RUBBERY' WOOD; (*b*) NORMAL WOOD. × 180.

Histological investigations carried out at East Malling Research Station have shown that the flexibility of the stems is associated with a lack of lignification of many of the xylem fibres and vessels. Lignification appeared to be normal in one-year old lateral shoots from 'rubbery' branches, except for occasional small areas near the cambium. In older shoots, and in the main stems of one-year old trees, most of the summer wood was unlignified, the spring wood alone giving the usual reactions to lignin stains; but even the spring wood was found to be unlignified in some very severely affected shoots more than two years old. This lack of lignification can be seen by the naked eye when a cross-section of the wood from a living branch is suitably stained, for example, with a 0·5 per cent solution of phloroglucinol in concentrated hydrochloric acid. The pale unstained areas of unlignified tissue contrast with the red-stained normal wood; the phloem and pericycle fibres were normally lignified in all the affected specimens (Fig. 1).

In the unlignified areas the walls of the vessels and fibres gave the usual staining reactions of cellulose. The vessels had irregularly shaped walls and some had collapsed altogether (Fig. 2). The xylem fibres were more or less circular as seen in transverse section, with abnormally thick walls surrounding a very small central cavity. In general appearance they resembled the description of the gelatinous fibres of tension wood[4]. Their distribution within the stem was, however, different, since the bands of gelatinous fibres in tension wood have seldom been observed to pass round the whole stem, whereas in 'rubbery' wood they often did so.

A similar lack of lignification has recently been observed in 'rubbery' branches from trees of the apple varieties, Miller's Seedling, Dartmouth Crab and James Grieve. The affected plants of the first two varieties were growing near trees of Lord Lambourne known to be 'rubbery'.

In conclusion, we should like to thank Dr. T. Swarbrick (Long Ashton Research Station), Mr. G. M. Stuart (East of Scotland Agricultural College), and Messrs. Chandler and Dunn (Canterbury), who kindly provided some of the specimens.

Pressure Units

THE recent communication by Dr. W. R. G. Atkins[1] directs attention to a considerable amount of confusion which still exists in statements of numerical results and constants. I suggest that one major change which is desirable is to adopt the bar as the unit of pressure in place of the millimetre of mercury.

In favour of this proposal the following considerations may be advanced: (1) The bar is an absolute unit (10^6 dyne cm.$^{-2}$). (2) The unit is already in use, and this use appears to be extending; for example, meteorological readings are expressed in millibars, intensity of sound in dyne cm.$^{-2}$, compressibility in bar^{-1}. (3) In calculations it is often necessary to work in C.G.S. units, involving the conversion of mercury units; for example, in measurements of surface tension or viscosity by methods which involve readings of pressure, and in thermodynamics. (4) The statement of results in terms of the bar avoids the possibility of some degree of indefiniteness when temperature and latitude are not stated, and simplifies statements by removing the necessity for specifying such conditions. (5) The present time presents probably the most favourable opportunity for making such a change, as a large number of new text-books, and revisions of older works, may be expected shortly. (The proposal would fit in with the suggestion made by F. H. Townsend[2] for a new system of high-vacuum units, which could be based on the millibar.)

Against the proposal are the following points. (1) Measurements of pressure are often (but not always) made by means of manometric pressure gauges. (2) A large number of physical and chemical constants are already calculated in terms of mercury pressure.

In answer to the first objection it may be suggested that as, for accurate work, it is necessary in any event to correct for temperature and gravity, no extra labour is involved, since the product of the density of the manometric fluid at a standard temperature and g would be a constant of the apparatus. It would appear to be as easy for an apparatus maker to graduate a mercury gauge in millibars as in millimetres.

With regard to the second point, the constants concerned include: (*a*) A comparatively small number of important constants, such as the gas constant for particular gases, and related constants, which could be converted very simply; for example, the volume per mol. of a perfect gas becomes 22,712 c.c. at one bar, instead of 22,415 c.c. at 760 mm. (*b*) A larger number of readings of vapour pressures, etc., where the measured constant is itself a pressure. Pressures given in reference tables would have to be converted to millibars, etc., and this labour migh present the chief obstacle to the adoption of th proposal. (*c*) A very large number of constant including the International Temperature Scale an tables of boiling-points, the values of which depen on pressure and are given for a specified pressure In most cases there is no need to recalculate thes quantities immediately—they can be quoted fo 1·01323 bar instead of for "760 mm. Hg at 0° C and lat. 45°."

Finally, for approximate conversion from units o mercury pressure to absolute units, it may be note that 1 bar is equivalent to 750·08 mm. of mercury (approx. 75 cm.—a point which may interest thos who teach elementary science).

The 'Green Flash' at Sunset with a near 'Horizon'

IT is frequently assumed that the phenomenon o the 'green flash' can be observed only when the sun is seen to rise, or to set behind a distant land- or sea-horizon. That such is not the case, the following report of a recent naked-eye observation will confirm.

At 20h. 12m. U.T. on June 20, 1945, I observed the sun setting behind the horizontal roof-line of a building distant approximately 440 yards from the site of observation. Immediately prior to the disappearance of the last remaining segment of the sun's limb, its colour was seen to change from light orange-yellow, through yellowish-green, to a distinct, but pale, green. At the instant of disappearance I observed the rapidly diminishing bead of sunlight to assume a just perceptible blue-green hue. On account of the large parallax introduced by the short distance from the artificial horizon, it was possible to repeat the observation by standing on tiptoe. The complete sequence of colour changes occurred in a time interval estimated to last from one quarter to one half of one second. It was noted that each of the transient colours was markedly less saturated than those which I had observed against a distant land-horizon on several occasions during the summer of 1940 from the summit of Mount Hamilton, California.

A rough estimate indicated that the altitude of the terrestrial obstacle was rather less than one degree above the true horizon on a bearing due north-west. On the evening in question there was a light southerly wind with a cloud cover of 2/10–3/10 *Ci*, the sky in the direction of the sun being entirely free from cloud. Horizontal visibility was excellent; I estimated the range to be in excess of ten miles.

Using an opera-glass to screen off unwanted light, Whitmell[1] has reported an observation of the green flash with the 'horizon' distant only 300 yards, but I have not been successful in finding any reference to naked-eye observations over so short a range as that recorded in the present note.

VISCOSITY OF LIQUIDS AND COLLOIDAL SOLUTIONS

1940 there was held in Moscow, under the auspices of the Academy of Sciences, a conference on riction and Wear in Machinery". At this confere it was decided to hold a further conference, in following year, on "Viscosity of Liquids and loidal Solutions". This took place just before the rman invasion and only a part of the proceedings e volume) was published before the serious events the first months of war made further publication porarily impossible. The second volume finally peared in a war-time format, in 1944 (Moscow d Leningrad: Academy of Sciences, 1941 and 44).

The subject-matter is divided into four separate tions: (1) theory of viscosity of liquids; (2) cosity of greases; (3) viscosity of molten materials high temperatures; (4) viscosity of colloidal utions. The first section is under the general torship of Prof. B. V. Deryagin, the second of of. D. S. Velikovskiĭ and the third and fourth of of. M. P. Volarovich, who is already well known to itish rheologists through his papers in the *Kolloid itschrift* dealing with an extremely wide range of terials. The two volumes contain more than enty papers in Russian; there are no summaries other languages.

Typically, there was no divorce between theory d practice at the conference. Some of the papers highly theoretical, with an advanced matheatical approach: others describe experimental idies on practical problems of immediate importce in industry.

Frenkel'[1] provides two papers showing the relationip between current theories of liquid structure. ere is also a short general note by Bachinskiĭ. irokov studies viscosity (η) as a wave phenomenon d deals with the theoretical aspects of heat conictivity. He also discusses the phenomenon of perfluidity, on which Kapitza provides an experiental paper on liquid helium; and Landau, a short scussion on quantum lines.

A theoretical study of the effect of magnetic and ectric fields on the viscosity of anisotropic liquids d molecular orientation is given by Tsvetkov; d Chernyuk has extended the work of Sokolov and sinskiĭ[1] on the influence of static fields on the scosity of organic liquids. In almost all the materls studied, there is an increase in viscosity with creasing field strength. Dombrovskiĭ shows marked creases in viscosity over a wide temperature range a result of sound-wave and ultrasonic radiation. the case of oils, Panchenkov increases viscosity y radiation with 'ultra-short' electromagnetic diation and by electrode-less high-frequency disharge. The chemical factors concerned are discussed d precautions are described to prevent overheating sulting in cracking of the oil.

The temperature- and pressure-coefficients of vissity are dealt with by a number of authors. Kobeko, uvshinskiĭ and Shishkin give $\log \eta / \frac{1}{T}$ curves for ther, alcohols and glycerine and many salt solutions T is absolute temperature). On the whole, they onclude that existing theory is inadequate and that n entirely new theory of liquid structure is required. amaya gets remarkably good linearity plotting temperature- against pressure-coefficients for lubricating oils.

Liquid mixture laws are dealt with by many authors. Luchinskiĭ develops an extension of the Bachinskiĭ equation which proves satisfactory for chloroform-benzol and sulphuric acid-toluol mixtures. Frenkel' discusses the general theory, and Voskresenskaya, Ravich and Shternina its application to physicochemical analysis. Udovenko distinguishes 'rational' and 'irrational' systems. For the former, isotherms can be resolved into two hyperbolic curves: for the latter the log η/temperature curve for the mixture shows no correlation with those of the components. Usanovich stresses the advantages of differentiating S-shaped mixture-curves, thus obtaining curves with simple maxima.

Single-figure expressions for viscosity-temperature coefficients of oils are badly needed. The 'viscosity index' comes in for considerable criticism, especially from Peĭsakhodina, Shne'erova and Tarmanyan working at low temperatures. Velikovskiĭ discusses the use of the Walther equation. There is also a useful technological paper by Zherdeva, Vozzhinskaya and Fedose'eva. The history of the $\log \eta / \frac{1}{T}$ equation is given very fully by Volarovich in a general survey of the theory of liquid structure.

On the instrumental side, Volarovich provides a survey of viscometers for petroleum products, with an excellent bibliography of papers from many countries. It appears that Soviet workers are more familiar with British and American work than British men of science are with the Russian; and the need for a wider knowledge of the Russian language among British rheologists is here strongly evident. Golenev gives comparative data for viscometers of the Ostwald and Engler types, and Shvidkovskiĭ develops further the earlier analyses of Andrade and Chiong[2] and Andrade and Rotherham[3] on the Meyer viscometer[4], a hollow cylinder containing liquid, hung on a torsion wire. A capillary viscometer suitable for oil and the choice of oil viscosity standards are discussed by Pinkevich. Deryagin and Samygin measure the viscosity of polymolecular films of liquids by observing the movement of air bubbles in the annular space between concentric sealed tubes under varying intensities of centrifugal force. There are three papers by Trapeznikov on monolayer viscosity, one of which shows complex curves relating η to stress and log η to temperature for high alcohols. Limar' describes an apparatus to measure the pumping properties of oil and discusses the relation between these and viscosity; and Ramaya regards the viscosity of oil containing added substances as analytically composed of two parts, a Newtonian and a thixotropic component.

The second section, on grease, contains a number of excellent papers. Greases are such complex systems that it is hard to find any single factor to describe consistency even for comparative industrial purposes. The work of Arveson[5] and of Blott and Samuel[6] is widely quoted. Varentsov uses the Scott Blair[7] emptying tube viscometer. He plots the wall stress against $4/RT$ where R is radius and T is the time taken for the meniscus to pass unit length of the tube. This is simpler than the usual method of plotting, which involves the difference in the squares of the initial length of the column and that at the time in question. Even plotting log-log gives complex curves, and the use of the method is restricted to low pressures and for comparative purposes. Velikovskiĭ uses the same method. He prefers to designate the consistency of grease by its 'mechanical equivalent', that is, the viscosity of an oil which requires the same force to produce an equal rate of flow under arbitrarily fixed conditions. Varentsov also calculates a shear modulus (γ) from Philippoff's[8] modification of the Eisenschitz formula:

$$\eta' = \eta_\infty + \frac{\eta_0 - \eta_\infty}{1 + \frac{2}{3} \cdot \frac{P^2}{\gamma^2}}$$

where η' is observed viscosity; η_0 and η_∞ are limiting viscosities at low and high shear rates; P is pressure.

There are also a number of useful technological papers on the rheology of greases. Rebinder, Boguslavskaya and Moki'evskiĭ find that the yield-value is independent of capillary radius which serves as a useful criterion of consistency.

There has been considerable discussion between British and American rheologists on the nomenclature of consistency of non-Newtonian systems. Velikovskiĭ proposes to use the term 'internal friction' (*Vnutrene'e treni'e*) to describe the ratio of shear stress to rate of shear when this is not independent of stress or shear rate, but the symbol η is used for both this and (constant) viscosity.

The section on molten lavas, melts and slags is perhaps rather less interesting, the data consisting mainly of viscosity-temperature curves with little theoretical comment. Exceptions are papers by Volarovich, who discusses the relative merits of various viscometers for molten metals and silicates; Kozakevich, Leĭba and Komar' (binary and ternary mixtures of FeO, CaO and SiO_2); and Semik, who studies the effect of addition of bases on the anomalous viscosity of surface layers of steel foundry slags. There are four good papers on the viscometry (mainly rotational instruments) of molten glasses: Fromberg, Tsyplënkova and Rabinovich; Oshchipkov and Rabinovich; Solomin; and Kumanin, Fizhenko and Zelichënok.

In the colloid section, there are two excellent papers on theoretical rheology by Finkel'shteĭn and Chursin, and by Rebinder; the former deals with extensions to the Einstein equation and the latter relates colloidal structure to types of flow curves. On the technological side, Branopol'skaya has a good paper on the rotation-viscometry of flour doughs, and Ravich gets a linear relation between η of high fatty acids and iodine number. There are also papers on the rheology of high polymers (Kargin and Slonimskiĭ), casein (D'yachenko), bitumens (Korotkevich) and coal tars (Kustov and Khotuntsëv). Kulakov is already known to rheologists interested in peat, and he contributes a paper on the relative merits of capillary, rotation and ball viscometers for this material. The first two methods are preferred to the ball. Serb-Serbina and Baranov have articles on the influence of electrolytes on the viscosity of clay suspensions.

In so brief a survey, one can do no more than sketch in the outlines of the contents of these books: many papers cannot even be mentioned. It is a pity that the whole proceedings cannot be translated into English. The conference undoubtedly marked a milestone in the progress of rheology, and it is to be hoped that when the War ends, language difficulties will not hinder a closer co-operation and understanding between British, American and Sovi rheologists as well as workers in the smaller countri

HEALTH RESEARCH IN INDUSTR

THE health of the industrial worker has recent been the subject of a number of articles in t medical Press, and various aspects of it have be also discussed by medical societies. Attention h been directed to it by the endowment by the Nuffie Foundation of three university departments of indu trial health; and the national importance of th field of study is further emphasized by the issue th year of two important publications. These are t second interim report of the Social and Preventiv Committee of the Royal College of Physicians London and the Medical Research Council's public tion entitled "Health Research in Industry", whic records the proceedings of a conference on industri health held at the London School of Tropical Medicin during September 1944.

The report of the Committee of the Royal Colleg of Physicians is part of this Committee's study social and preventive medicine. Its first interi report dealt with the applications of this study i the hospital. This second interim report is the firs step in the study of social medicine outside th hospital. As the *British Medical Journal* (194 Feb. 10, 1945) points out, this report fills a ver obvious gap, because the Government's White Pape on national health does no more than state th present position of industrial health and does that i no more than one short paragraph and an appendix If, says this second interim report of the Roya College of Physicians, the Government's plans for th establishment of a sense of social security are t succeed, industrial production must be efficient; an efficient production requires contented workers, an they cannot be contented unless they are physicall and mentally fit. A third of the working years o most workers is spent in the places where they work and their working and home life affect each other s profoundly that each individual's whole life must b considered.

This Committee prefaces its recommendations by a useful outline of the development of British industrial medicine. Existing industrial medical services apply only to a small proportion of industrial workers at their places of work. It is in the smaller factories that it is usually difficult to maintain good working conditions. Factory inspectors, both lay and medical, have done magnificent work, but four hundred inspectors (including the sixteen medical ones) and the two hundred whole-time and seven hundred part-time works doctors cannot adequately supervise th health of the 250,000 establishments covered by th Factories Act of 1937. The Factories Acts do no ply to many industries and to others only certain tions of them apply. Some large businesses and me transport services (for example, railways and cks) have their own works doctors; but medical vices are most deficient outside factories where ey are needed most. Existing services are not equately co-ordinated. Control is shared by the ome Office and Ministry of Labour, while the nistries of Supply and of Fuel and Power have eir own independent medical services, and other w Ministries may create theirs. A national comehensive industrial medical service is required; it ould be organized on a regional basis as an essential rt of the national health service, with ultimate sponsibility vested in the Ministry of Health, hough certain administrative and executive funcons would no doubt have to be allocated to the inistry of Labour and National Service, the Minisies of Fuel and Power and of War Transport and e General Post Office. The Committee hopes that e Government will not adhere to its temporary clusion of industry from its national health heme, which lays a just emphasis on the family as unit for medical care and extends medical care to e home as well as to the place of work.

Everyone will agree with this Committee's strong ea for much better medical care for smaller industies, such as hotels, restaurants, shops, offices, the ilding trade and agriculture; and for recognition the fact that occupational disability and disease use only a fraction of the total illness of the workers, ho lose about fifteen times as many working hours the result of non-industrial sickness and accident they lose from industrial causes of disability; is estimate excludes, moreover, the considerable fects of subnormal health. Much preventable isease is due to factors operating outside the place work, such as bad housing, economic stress and ck of health education. Continuous medical investiation is necessary and the co-operation of the anagement is important. Rehabilitation, which has gured largely in the medical Press recently, is mphasized by this Committee, which strongly suport the Government's White Paper on Workmen's ompensation (Cmd. 6551), which would do much to stablish rehabilitation as part of the national health heme.

In its discussion of the planning of the education f medical men for industrial health work the Comittee refers to its first interim report, repeating that he medical student is not expected to become an xpert on occupational diseases, but should undertand the social problems involved and should ecognize the effects of fatigue, overwork, monotony nd other factors causing ill-health in industry; he hould therefore visit factories and should have good nd bad working conditions demonstrated to him. ere the reader of this report is reminded of the oodenough Report on Medical Schools (*Nature*, **154**, 15 and 322, Sept. 9, 1944). The family doctor hould, the Committee of the Royal College of hysicians thinks, be trained as a part-time industrial edical officer, and periodical refresher courses on his subject should be available for him. More xtensive training is planned for whole-time indusrial medical officers; this should not be too specialzed and should not be taken until two years after raduation and after one year of general practice. onsultants and specialists should be subject to the riteria for the recognition of consultants and pecialists laid down by the three Royal Colleges.

The section on research with which this report concludes links it with the Medical Research Council's publication mentioned above, which outlines the development of the Industrial Health Research Board of the Medical Research Council. The Committee of the Royal College of Physicians commends the work of this Board and its parent organizations and wishes that work to continue. The Board should, this Committee thinks, tackle problems of national significance and also problems which cannot be undertaken by other research organizations. Fundamental research should not be neglected; it should be done by the university departments of industrial health which are now being created, and these should correlate their work with that of the Industrial Health Research Board and with that of the local factory department. Co-ordinated with all these there should be, in each local administrative area set up under the national health scheme, a division for field investigation.

The work of the Industrial Health Research Board was reviewed at the conference mentioned above by Sir Edward Mellanby, secretary of the Medical Research Council. Sir Edward commended another review of it by Dr. Schelling in the *British Journal of Industrial Medicine* (1, 145; 1944). Reconstituted in 1942 by the Medical Research Council, the Industrial Health Research Board was given the study of the whole field of industrial medicine and disease, and it is expected that it will act in an advisory capacity in relation to all the problems being studied by the Medical Research Council itself. The Medical Research Council has organized much work on industrial health. During the War much research has been done for all the Fighting Services, and many of the principles learned during this work can be applied to industry. As examples of this application Sir Edward referred to the work done on blood transfusion, on traumatic shock, and on the problem of fitting men to the machines which they have to use and of fitting the machines to the workers.

The problem of recording causes of sickness absence in industry is fundamentally important. The Industrial Health Research Board's Report No. 85 (1944) deals with this problem, while Report No. 86 (1945) records a study of certified sickness absence among women in industry. Certified sickness absence for two or more days was studied in five munition factories, but uncertified sickness absence, which may or may not be genuine, was excluded. Other reports on this subject are to follow and they will include the views of the workers themselves. Other problems being studied are night work, atmospheric pollution in filling factories, new methods of sampling T.N.T., the efficiency of dust-sampling instruments, lighting problems and the incidence of psychoneurosis. Another example of the work of the Medical Research Council which has valuable applications to industry is the valuable report recently issued on the treatment of burns and scalds (Med. Res. Council Spec. Rep. Ser., No. 249, 1944. H.M. Stationery Office, 4*s.* net). This work records the conclusions drawn from observations made during recent years by the Medical Research Council's Burns Unit working at Glasgow Royal Infirmary. Another unit is working at Birmingham on infections to which injured industrial workers are liable.

The work of the Department for Research on Industrial Medicine, which was set up at the London Hospital by the Medical Research Council, was described to the conference by its director, Dr. Donald Hunter, who also edits the *British Journal of*

Industrial Medicine. An article by Dr. Hunter on industrial poisons was reviewed in *Nature* of April 1, 1944, p. 412; but Dr. Hunter pointed out that industrial poisons form only a relatively small part of the field of industrial medicine. His department is also studying the effects of inhalation of asbestos and other dusts, the 'dead hand' from which users of pneumatic tools often suffer and the effects of some of the appalling industrial noises, such as that which has made generations of boiler-makers deaf. Dr. Hunter also discussed rehabilitation, pointing out that many jobs can be done by men with chronic disease of the heart, lungs and nervous system and quoting Henry Ford's remark that there are more jobs in industry for men with one arm than for men with two.

The views of enlightened managers were given to the conference by Lord Forrester, managing director of the Enfield Cable Works, Ltd., and a distinguished worker in industrial and social fields, who emphasized the importance of a healthy environment for the workers and of a right integration of industry with the community to which it belongs. Research into management and the teaching of management are also required. Research teams composed of young men are essential and Lord Forrester suggested problems for them. One of these is the problem of posture in industry. The position of the operator is considered in the construction of tanks and aeroplanes, but surprisingly little attention has been given to it in industry. In the discussion which followed Lord Forrester's address, Sir Wilfrid Garrett, chief inspector of factories, told the conference that a committee has recently been appointed to study this problem. Lord Forrester thought that we need a better system of keeping industrial health records. We should abandon all systems of calculating working time in hours per day or week; we should think in terms of at least a year. Shift work is another problem requiring study; the worker should have the right kind of food, and time and leisure to eat it in suitable surroundings. Sanitation and hygiene are of high significance; yet the very important question of lavatory design is almost universally ignored. The town planner, the industrialist and the industrial health expert must get together to study the problem of the environment of industry itself. The smoking chimney and similar sins must go. Loss of green sward has important effects on the health of the people. Industry need no longer disfigure the land, or pollute its atmosphere and rivers; nor need its physical appearance be an abomination.

The point of view of the trades unions was put to the conference by Mr. G. A. Isaacs, general secretary of the National Society of Operative Printers and Assistants and president of the Printing and Kindred Trades Federation, chairman of the Workmen's Compensation and Factories Committee of the Trades Union Congress, and a member of the Royal Commission on Workmen's Compensation. He pointed out that the trades unions have studied industrial health for many years and gave examples of the improvements which they have achieved by their own efforts. He did not wish it to be thought that he was complaining about the work of the Home Office and Factory Department of the Ministry of Labour, which had, he insisted, done good work and had often acted when the Trades Union Congress had little information; but they had not the complete research organization which the trades unions considered essential. Research should have ample mon staff and equipment. Eradication of industrial hea risks was required, not mere recognition of and co pensation for them. Prompt, accurate and scient decisions were required as to what were and wh were not occupational diseases; such decisi should not be subject to argument in a court of la The worry caused to workers by industrial injur had been revealed in conferences called by the tra unions. Workers would always willingly help resear Mr. Isaacs suggested that more work was needed the effects of industrial fumes and dusts, on ventilat and lighting, on the effects of monotony, fatigue noise and on the risks of welding. He stressed, Lord Forrester also did, the need for communicat the results of research to the workers themselve language which they could understand.

At the final session of this conference Dr. K. J. Craik described the work of the Cambridge Unit Applied Psychology, of which he was direc until his untimely death on May 7. This Unit been studying problems arising from the needs the Services, but some of the principles learn during this work can be applied to industry. Th are, for example, the problems of suiting the j to the man, suiting the man to the job and i proving performance. The problem of suiting t man to the job includes the study of the design machinery and instruments and their lay-out a illumination by maps, panels and so forth. T position, forces and gear ratios of handles, levers a other forms of control are being studied, togetl with methods of getting the best results in jobs o boring but responsible nature. The effects of fatig discomfort and noise and the intellectual aspects industrial work also need study. This Unit h attached to it an Industrial Research Board tea which has devised tests of mechanical ability a of performance and other qualities; it is studyi night vision, the capacities of blinded office problems of the special senses and temperament differences in the ability to control machinery. F the study of the improvement of performance has invented devices which will be useful in indust after the War. A new type of recording system h been invented for the tracing of causes of absenteeis sickness and accidents, and this is being establish in a group of coal mines and in two factories. Th Unit hopes for the collaboration of the Nation Institute of Industrial Psychology and other bodi doing similar work and with managers, safety office and medical men. The Unit has a scheme by whi factories send to Cambridge representatives who c be trained there to study their problems in the own factories.

It will be clear from this brief summary of t contents of the important publications mentione that carefully thought-out plans exist for t amelioration and eventual eradication, wherever th is possible, of industrial health risks. It is evide that the workers will help industrial health researc by every means in their power and that the medic profession and many managers are no less eager solve this national problem. Not the least importa of its many aspects is the one to which Sir Edwa Mellanby referred. Much valuable information w obtained in the interval between 1918 and 193 but this information was largely left unnotic until the present War began. Then its value becan widely recognized and industrial health researc is now considered essential. Sir Edward warne s that this may be only a war reaction. We must, insisted, see to it that all who are concerned with dustry do not cease, after the War, the efforts ey are now making to create an efficient industry ased on the health and contentment of the industrial orker.

G. LAPAGE.

USE OF TREES AND SHRUBS AS FOOD FOR CATTLE

N many parts of the British Empire, the feeding of excessive numbers of low-grade stock has ecome a serious problem, not only for the forester ut also for the agriculturalist. In an article in the *ndian Forester* (Civ. and Milit. Gazette, Lahore, Dec. 944), J. A. Wilson, of the Madras Forest Service, iscusses the place of fodder from trees and shrubs the "Agricultural and Forestry Economy of adras", a problem to which many of the newly unded soil conservation committees in the Colonies d elsewhere will have to give serious consideration.

It has been the practice in India in the hot-weather eason and during serious famines to look to the rest for fodder for the villagers' often large herds f a very low type of cattle; the animals browsing n the trees, shrubs and young regeneration. "In ommon with the rest of India," Mr. Wilson writes, 'the cattle population of Madras is excessive; specially is this so in dry areas and areas of eserved forest, where cattle of low efficiency and ittle value can eke out a living at extremely low ost. . . . The concentration of scrub cattle in such reas, combined with the extension of agriculture to bsorb waste lands, previously at the disposal of the attle, has resulted in the complete denudation of grass cover over vast areas, except during the relatively short monsoon period. In the reserved forest f the dry districts also, the pressure of the grazing nimals is high, and marginal areas are for the most part badly overgrazed. While the agriculturalist provides for his utility animals during the hot weather he cannot afford to do so for his scrub animals. From February onwards therefore they have to depend on whatever cheap fodder they can pick up." From March onwards trees and shrubs put on new foliage, and the forest by the dual acts of browsing and lopping has to suffer to keep this low-grade stock alive.

It has long been the aim and the policy of the forest officer in India to bring to an end this gradual degradation and impoverishment of the forests, annually overgrazed under more or less direct orders from the civil government. The necessity, in the economic gain, for this long-continued practice is now being called in question, and not in India alone. More up-to-date management of the cattle is being considered, based on a sound soil and water conservation policy in all dry districts; improved pasture management over extensive areas of grazing grounds, involving a limitation of the head of cattle using the area and rotational closing; the storing of surplus monsoon fodder in hayricks and barns or by the preparation of ensilage.

In *La Forêt Quebecoise* (9, Jan. 1, 1945, Quebec), after an interesting account of the advent from Europe to New York and eventually to Quebec of the elm disease and the large loss of trees sustained, an author has a most valuable article on this question of forest pasturage under the title "Méfaits du paturage" with some excellent illustrations, which demonstrate his contention that unchecked grazing and browsing in a forest means its ultimate extinction owing to the impossibility of maintaining successful regeneration to replace the old trees. "La Forêt," says the author, "ne peut servir de paturage et rester en même temps productive. Soumise à cette pratique désastreuse elle abandonne infailliblement sa fonction principale qui est de produire du bois ou de la sève, et elle ne fournit en même temps qu'une pâture de bien pauvre qualité."

ELECTROMECHANICAL ANALOGIES

ELECTROMECHANICAL analogies and their use for the analysis of mechanical and electromechanical systems form the subject of an interesting paper (*J. Inst. Elec. Eng.*, 92, Pt. 2, No. 52; April 1945) by Dr. A. Bloch. After some introductory remarks which outline the problem and special features of its treatment, the author explains how the complex notation and the impedance concept can be applied directly to the analysis of mechanical systems. This leads naturally to the first or 'direct' method of constructing an electrical 'model' of a mechanical system, where a mechanical force is represented by a voltage, and a mechanical impedance, that is, the ratio of a force to a velocity, is then represented by a proportional electrical impedance. In this analogy a mass is represented by an inductance. It is shown that this representation, when established for one particular frequency, is valid for all other frequencies.

There exists a perfectly consistent alternative method of constructing such an electrical model in which all these correspondences are replaced by their dual counterparts and which is therefore called the 'indirect' or 'inverse' analogy. A mechanical force is here represented by an electric current and a mechanical velocity by a voltage. Accordingly, a mechanical impedance is then represented by an electrical admittance of proportional magnitude; in particular, a mass is represented by a capacitance. This analogy has the advantage that it enables a circuit diagram of the electrical model to be copied from the diagram of the mechanical system, if this be drawn in accordance with certain conventions. The circuit diagram found by this method is the dual of the circuit found by the first method; and as it is a routine procedure to draw the dual of a given network, the second analogy may also be useful when utilizing the first type of analogy.

The paper supplements the development of this method by showing how levers fall into the general scheme of this geometrical correspondence if they be interpreted as auto-transformers. It also shows how the circuits of both these analogies may be found with advantage by an alternative method, that of a 'method of successive generalization' of simplified systems—again without the need of establishing the equations of performance of the system. When the circuit of the inverse analogy cannot be drawn in a plane without crossing between its branches, certain difficulties arise the solution of which is dealt with in a separate paper to be published elsewhere.

Combined electrical and mechanical systems are next discussed in the paper. If the mechanical system is represented by an electrical model, then the electromechanical converter which links it to the electrical system can usually be replaced by a passive electrical four-terminal network (provided the right type of analogy be chosen for constructing the model), and in this way a purely electrical system is reached. The type of analogy to be chosen is the direct one if the electromechanical converter utilizes the action of the electrostatic forces, and the inverse analogy if the converter utilizes electromagnetic forces. Two appendixes give examples of the application of these methods to the treatment of purely mechanical and of electromechanical systems.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Master to teach Mechanical Engineering Subjects in the Redhill Technical College to Ordinary National Certificate, and also Engineering Subjects in the Junior Technical School—The Clerk to the Governors, Education Department, Town Hall, Reigate. Surrey (August 10).

Lecturer in Organic Chemistry, and a Lecturer in either Analytical Chemistry or Physical Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (August 11).

Teachers (2) of Mechanical Engineering Subjects to Higher National Certificate standard, in the East Ham Technical College—The Chief Education Officer, Education Office, Town Hall Annexe, Barking Road, London, E.6 (August 11).

Engineering Editorial Assistant for work in London—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting C.2454.A (August 11).

Engineers (mainly Civil Engineers), Chemists, Physicists and Architects, at the Building Research Station, Garston, Watford, Herts, for research and other technical work on building—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting D.S.I.R. (August 11).

Assistant Lecturer in the Department of Economics—The Registrar, University College, Singleton Park, Swansea (August 11).

Chemistry Master in the Secondary Technical School—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (August 13).

Principal of a Training College for Technical Teachers which is to be set up in Lancashire in the near future—The Secretary, Ministry of Education (Teachers' Branch), 14–22 Lennox Gardens, London, S.W.1, endorsed 'R.E. (Technical Appointment)' (August 13).

Teacher of Engineering Subjects, particularly for Electrical Sciences in the Day School and Electrical Engineering in the part-time day and evening classes for National Certificate, City and Guilds Courses, etc., in the Cambridgeshire Technical College and School of Art—The Chief Education Officer, Shire Hall, Cambridge (August 14).

Lecturer in the Science Department (duties to include instruction of classes in Mathematics to Degree standard with, if possible, Physics as subsidiary subject)—The Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (August 15).

Lecturer in Electrical Engineering, with subsidiary Mechanical Engineering—The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15 (August 15).

Assistant Lecturer in the Physics Department—The Registrar, University College, Southampton (August 15).

Assistant Lecturer (Grade III) in Philosophy—The Secretary, The University, Birmingham 3 (August 15).

Economics Officer (male)—The General Secretary, National Farmers' Union and Chamber of Agriculture of Scotland, 6 Ainslow Place, Edinburgh 3 (August 15).

Donald Pollock Readership in Engineering Science—The Registrar, University Registry, Oxford (August 20).

City Electrical Engineer—The Town Clerk, Guildhall, Bath (August 22).

Psychiatrist (temporary) to the Child Guidance Clinic of the Oxford School Medical Service—The Chief Education Officer, 77–79 George Street, Oxford (August 23).

Assistant Lecturer in Civil and Mechanical Engineering—The Acting Registrar, Queen Mary College, Mile End Road, London, E.1 (August 24).

Agricultural Chemist (woman) in the Department of Agriculture, Government of Sierra Leone—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting F.4342.A (August 25).

Director of the Department of Social Studies in the University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (August 31).

Senior Lecturer in Social Anthropology in the Department of Bantu Studies, University of the Witwatersrand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (August 31).

Lecturer in Geography—The Secretary and Registrar, The University, Bristol (August 31).

Assistant Lecturer in Mathematics—The Registrar, The University, Sheffield (August 31).

Assistant Lecturer (Grade III) in Geology, with qualificat in Palæontology and Stratigraphy, and a Lecturer (ungrad in Social Science—The Registrar, The University, Liverp (August 31).

Chief Electrical Engineer to the Bristol Corporation Electric Department—The Deputy Town Clerk, Central Library, Coll Green, Bristol 1 (August 31).

Assistant Lecturer and Demonstrator in the Househo Arts Department—The Secretary, King's College of Household a Social Science, c/o University College, Leicester (September 8).

Headmaster—The Secretary, King Edward's School, Edgbast Park Road, Birmingham 15 (September 15).

Sir Homi Mehta Reader in Plastics, Paints and Varnish and Singhanee Lecturer in Chemical Engineering, in the Depa ment of Chemical Technology—The University Registrar, The U versity, Bombay, India (September 15).

Wykeham Professorship of Physics (theoretical)—The Registr University Registry, Oxford (September 29).

Assistant Lecturers (2, Grade III) in Applied Mathematic The Registrar, The University, Liverpool (October 1).

Lecturer in Philosophy in the University of Melbourne—T Secretary, Universities Bureau of the British Empire, c/o Univers College, Gower Street, London, W.C.1 (October 15 in Melbourne).

Chair of Psychiatry tenable at the Maudsley Hospital—T Academic Registrar, University of London, Richmond College, Ri mond, Surrey (November 5).

Lecturer in Mining and Allied Subjects—The Principal, Coun Technical College, Blyth Road, Worksop, Notts.

Lecturer in Physics to Inter. B.Sc. standard—The Princip Guildford Technical College, Guildford, Surrey.

Lecturer (part-time) in Chemistry (Matriculation and Int standard) at the Plymouth and Devonport Technical College—T Director of Education, Education Offices, Plymouth.

Assistant Lecturer and Demonstrator in the Physics Depar ment—The Secretary, King's College of Household and Social Scien c/o University College, Leicester.

Librarian—The Secretary, Woolwich Polytechnic, Woolwic London, S.E.18.

Laboratory Technician (Biochemical Analysis), preferably wi experience in Micromethods—The Hon. Secretaries, Royal Hospit for Sick Children, Edinburgh.

Laboratory Technician (Grade B) for work involving the chemic estimation of vitamins—The Secretary, National Institute for R search in Dairying, Shinfield, Reading.

Mechanical Inspector of Works (temporary) by the Govern ment of Sierra Leone, for the Electricity Branch of the Public Work Department—The Ministry of Labour and National Service, Appoin ments Department, Sardinia Street, Kingsway, London, W.C. quoting Reference No. O.S.605.

ATOMIC ENERGY: AN INTERNATIONAL RESPONSIBILITY

THE announcement by President Truman on August 6 that the United States Air Forces have used an 'atomic bomb' against the Japanese army base at Hiroshima was accompanied by the issue by the Prime Minister of a statement prepared by Mr. Winston Churchill some time ago on the history of the plans made in connexion with this project. The early stages of the research work involved were carried out mainly in the universities of Britain, particularly at Oxford, Cambridge, the Imperial College of Science and Technology, Liverpool and Birmingham. The Ministry of Aircraft Production was responsible for the work, being advised by a committee of scientific men. In 1941 the project was brought before the Chiefs of Staff Committee, which gave it the maximum priority.

At this time a special division of the Department of Scientific and Industrial Research was set up to direct the work, which was given the title of Directorate of Tube Alloys; and a consultative council and a technical committee were appointed. Both university and industrial laboratories were pressed into service; throughout, leading men in Britain associated with the physics and chemistry of atomic structure were brought in. In the autumn of 1941, President Roosevelt suggested closer relations with American men of science working on the same subject, as a result of which there was a fusion of efforts and several workers went from Britain to the United States to continue their researches. A year later such progress had been made that it became necessary to decide where the enormous plants which would apparently be necessary for large-scale production should be erected; since Great Britain was already fully occupied and on account of the relative security from interference afforded by the United States, that country was chosen. Most of the prodigious cost now fell on the United States. Canada also came in, providing part of the raw material and facilities for one section of the work.

Such is the bare outline of the genesis of the atomic bomb, the secret of which was well kept. But the matter cannot be allowed to rest there. On the face of it, some of the ablest scientific brains of the United Nations have been devoted for a period of years to the production of an engine of destruction; this is not, however, the whole story. For many years past it has been known that the break-up of the nucleus of an atom would lead to the release of great amounts of energy; and several writers with scientific knowledge and interests have based fascinating and almost prophetic stories upon the possibility of its achievement. During all this time scientific research has been going steadily on, step by step, delving into the interior of the atom. In time, there can be no doubt that the release of atomic energy would have been achieved; but the outbreak of war, with its threat to the world, made atomic energy a prize which would speedily sway the battle, and men and resources were provided regardless of cost. As in many other cases which could be quoted, war sharpened the interest in research of those who control the public purse, and as a result every facility was provided for promoting an investigation which in peace-time would probably have received scanty support. It is known that the Germans as well as ourselves were seeking the solution ; but, fortunately for the world, they were not able to achieve practical results.

Nevertheless, the very successfulness of the investigation induces a feeling akin to dismay that science should contribute such an engine of destruction to the world. This feeling must be put aside, though the possibilities must never be forgotten. We must remember that this new source of energy now being tapped, "long mercifully withheld from man", as Mr. Churchill wrote, can and must in the years of peace be harnessed to the needs of industry, to supplement the forms of power now in use. Research into the regulated release of atomic energy, if this has not already been achieved, will be carried on from a new basis and with redoubled energy. No doubt much painstaking work will be necessary before the new source of energy can be utilized in economic competition with fuel and wind- and water-power, but the present position clearly holds possibilities of the utmost significance.

There is another facet of the world situation which this scientific and technical development has brought to the forefront, namely, the immense responsibility now placed in the hands of those with exact knowledge of the steps necessary to release atomic energy. It has been stated that adequate measures have been taken to secure patents on all vital processes, and all rights in such patents have been assigned to the Governments concerned. At present, this must mean that the United Nations, and especially Great Britain, the United States and Canada, hold in their hands a weapon with which they can dominate the world—a responsibility the discharge of which will require the highest degree of statesmanship. They also hold a potential source of power capable of contributing immensely to the welfare and material progress of mankind—a further and even greater responsibility. How will they use it ? Governments are notoriously impersonal, and they come and go. It therefore devolves upon the individual, be he man of science or layman, to understand the potentialities of atomic energy, even if he comprehends little of the method of its release ; and to ensure that his elected representatives, from whom his Government is chosen, are also aware of their responsibilities in the matter. It is not a matter of exact knowledge so much as an appreciation of right and wrong in dealing with our neighbours, who are now every nation of the world ; indeed, the alternatives would seem to be an international brotherhood of nations or chaos. There can be no question of halting investigations until mankind is fitter to receive them ; if material research has outstripped the progress of knowledge of man, then the tempo of investigation of man as a social being must be increased until both can progress, side by side, carrying man onwards to the higher ideals of life for which the best of each generation are always striving.

MAN-POWER AND TRAINING THE SCIENTIFIC INSTRUMENT INDUSTRY

IN an article in *Nature* towards the end of 194 attention was directed to the dependence on live and efficient scientific instrument industry Britain of the hopes that the technical and resea resources and facilities of industry would be rais to a level which would allow of full application bei made of scientific knowledge and of advanceme in that knowledge. Further, it was pointed out th in no branch of industry is the need of techni knowledge and facilities greater than in the scienti instrument industry. At the time these observatio were made, the manufacturers of scientific instr ments and equipment were completely occupied fulfilling the demands of the Government in respe of war requirements and, indeed, this state of affa still persists. It is, however, reasonable to suppo that the post-war period now lies in the near, rath than in the distant, future, and it is opportune review the position of the manufacturers of scienti instruments and of laboratory equipment in relati to their ability to meet their vital commitments the nation during the period of the re-creation national prosperity.

Two factors which are vital to the efficient manu facture of scientific instruments and equipment a craftsmanship and technical knowledge in its wide sense and, while neither was in a very healthy con dition before the War, both have certainly bee adversely affected by the War. The desperate de mands on man-power of the Fighting Services durin the past six years have inevitably resulted in th scientific instrument industry, in common with a other industries, being engaged in a losing battl with the Ministry of Labour and National Servic for the retention of its craftsmen and technicians Moreover, for six years the industry has been en gaged in the mass-production of instruments fo Service use, and it will be appreciated that, excellen as the British war-time instruments have been, there is a vast difference between the delicacy of instru ments designed for accurate measurement unde reasonable conditions and that of instruments required to be as accurate as possible under the very robust conditions which must exist in the tank aeroplane and other engines of war. In consequence the craftsmen, generally those of mature age and experience, who have remained in the industry have not been required to exercise their craft to the full, and will, to some extent, have to regain their skill. As regards technicians, the demands of the research and development departments of the Services have been such that it has been impossible for the industry to avoid losing much of its technical personnel, and have prevented any recruitment being made by the industry to make good its technical deficiencies. Further, the large extent to which development has taken place within Service departments has reacted unfavourably on the maintenance of efficient development in the industry itself. The industry therefore faces its post-war commitments under the shadow of a very serious deficiency both in craftsmen and technicians; and, in view of the vital function of the scientific instrument industry in the national life, the position calls for serious thought and remedial action.

---

* *Nature*, 152, 704 (1943).

It has already been remarked that craftsmanship and technology within the scientific instrument industry—and indeed in all industries—have not been what they should or might have been; and it is an encouraging sign that there is a general recognition of this fact within the industry itself, and that serious consideration is being given to the means of ensuring a marked improvement in the future. It is evident, however, that any policy which may be adopted to this end must be a long-term one, for neither craftsmen nor technicians in sufficient numbers can be produced by any means other than by education and training over a long period. It is well that such a policy should be pursued, but it must be realized that three immediate tasks, which cannot depend on any long-term policy, confront the industry: the home demands for instruments and equipment in the industrial, educational and other civil spheres must be met, and it should be noted that the industry is already some two years behind in the fulfilment of orders; the industry must take its full share in the rehabilitation of the technical facilities of liberated Europe; the industry's export trade has to be recovered and extended, and it is relevant to observe that foreign governments have long realized that the scientific instrument is, from every point of view, the ideal article for export. If these tasks are to be carried out with some measure of adequacy, a short-term policy must be evolved which will ameliorate the conditions at present existing in the industry. The continuing war in the East must necessarily restrict the possibility of certain procedures being adopted, but it is well to state the actions which might be taken to instil confidence in the industry as it faces these tasks, and to increase its competence to carry them out. Three of these actions may be briefly stated. There are craftsmen in the Armed Forces whose service may continue for some considerable time: their release would confer great benefit on the industry. There are young craftsmen who have achieved a considerable degree of skill but who will normally be called up for service in the near future: their retention in the industry is most desirable. There are older and more mature craftsmen in the industry who have been long starved of the opportunity to exercise their peculiar skill in full measure: encouragement to the industry to recommence, even on a limited scale, the manufacture of its civil and export products would not only provide a preparation for production for the future, but also would furnish an excellent refresher course for these craftsmen. No such encouragement has yet been received.

What has been said of craftsmen applies, to some extent, to technicians, but the formulation of a short-term policy to meet the technical needs of the industry presents considerable difficulty. Scientific instruments and equipment are produced in Britain by relatively small firms which are distributed over the whole of the country, and, in consequence, it is almost impossible that adequate technical facilities should exist in every individual firm. Here then surely is a case in which, certainly for some years, a considerable proportion of the technical, and especially the research, facilities of the industry must be found in its research association. The British Scientific Instrument Research Association has evolved a scheme of expansion which, if quickly achieved, should go a long way towards covering the whole field of problems associated with the manufacture of scientific instruments. It would seem that in whole-hearted co-operation with its research association lies the best hope of the industry to resolve its technical difficulties, at least until any long-term policy to deal with the technological aspects of instrument production has had time to affect the situation.

Any immediate action which may be taken to meet the pressing need of the moment should in no way prejudice the pursuance of policies by the industry to overcome deficiencies in craftsmanship and technology. In a book recently published*, Mr. F. Twyman has described the rise and fall of the apprenticeship system and has put forward a passionate plea for its revival. It is only too frequently true that apprentices to-day receive no systematic instruction in their crafts but have of necessity to pick up their knowledge as best they may. The training of apprentices cannot be fully efficient while their work is considered to be an integral part of production, and it would be of inestimable worth to the industry if a scientific instrument apprentices school were established from which a steady stream of trained craftsmen could flow into the industry and thus provide a solid core of craftsmanship. The wide distribution of the industry renders any local system of training very difficult, but it is conceivable that united action by the entire industry might evoke the co-operation of the Ministry of Education and result in the establishment of a true school of apprenticeship for scientific instrument makers, which might effectively resolve the question of craftsmanship and would constitute a national asset. The provision of technicians in the industry will be vitally affected by the nature of academic and technical education in the future. In this connexion the recommendations of Lord Eustace Percy's Committee will be awaited with interest. Again, the hope may be expressed that in the post-war period a far more adequate liaison will exist between the academic scientific worker and the industrialist than has been the case in the past. The research association movement has now achieved considerable dimensions and a large measure of stability, and forms a very useful halfway house between science and industry. The research association would seem to provide a very convenient channel through which scientific men who desire to enter industry might well pass in their transition from academic to industrial life.

Long-term policies, however, cannot affect the immediate future. There is every reason to anticipate that victory over Japan will not be long delayed, and that, in the near future, industry in Great Britain will be called upon to make perhaps its greatest effort in order to secure the future well-being of the country. There is no more important tool in industry than the scientific instrument, and it is to be hoped that no unnecessary restriction imposed at the present moment will cause the manufacturer of scientific instruments to falter when the demand is made on him for the tools vital to the technical rehabilitation of our national life.

VOLCANIC FORMS AND STRUCTURES

Volcanoes as Landscape Forms

By Prof. C. A. Cotton. Pp. xv+416. (Christchurch and London: Whitcombe and Tombs, Ltd., 1944.) 32*s*. 6*d*.

It is no accident that the varied landscapes of New Zealand should have stimulated Prof. Cotton to enrich the literature of geomorphology with a series of books of outstanding interest and importance. In no other country of comparable size can a greater variety of geological agents and processes be seen in active operation, and since land-forms result from the interaction of the internal and external processes, it follows that New Zealand is a geomorphologist's paradise.

In his latest work Prof. Cotton gives us for the first time a detailed and systematic account of volcanic land-forms and their subsequent modifications. Along this line of approach, discussion of theories of vulcanism and petrogenesis is not to be expected. Nevertheless, the author devotes six introductory chapters (Part 1) to the mechanism of volcanic activity, and when he comes to volcanic landscapes (Part 2) he continues to adopt a treatment which, throughout the ten chapters dealing with the primary forms of construction and destruction, is quite rightly genetic as well as descriptive. The last two chapters, which deserve expansion and might well have formed a third part, are concerned with the erosion and dissection of volcanic plateaus and mountains. Volcanic contributions to atmosphere and ocean are briefly discussed in an appendix.

The author emphasizes the fundamental distinction between (*a*) dominantly lava volcanoes, mainly basaltic, and characterized by relatively quiet effusion; and (*b*) dominantly pyroclastic volcanoes, generally emitting more silicic materials and characterized by explosive eruptions, which not infrequently reach catastrophic intensity. An attempt is made to correlate this striking contrast in behaviour with the chemical compositions of the lavas concerned. Attention is directed to the importance of iron oxides in promoting mobility and high temperature (by reaction of Fe_2O_3 with juvenile hydrogen), and it is surmised that the high viscosity and lower temperature at which the more silicic lavas commonly arrive at the surface may be partly due to their lower content of iron. The development of this idea in relation to other elements is less happy. Thus, after suggesting that the peculiarities of the Vesuvius eruptions may be related to the highly potassic character of the lavas, the author goes on to say (p. 63): "The lava of Etna also is a potash-rich basalt, and the activity of Etna is not very unlike that of Vesuvius". Actually, the lavas of Vesuvius are leucite-tephrite with 7·5 per cent of K_2O, while those of Etna are andesitic basalts with only 1·6 per cent. Moreover, on p. 47, it is wrongly assumed that the dome-building volcanoes of central Africa are basaltic. Far from being basaltic, the lavas of Nyamlagira and Ninagongo are felspathoidal types with 3·5 and 5·5 per cent of K_2O respectively. These examples add point to the author's own warning (p. 63), based on the eruptions of Tarawera, "against too confident prediction of the eruptive properties of magmas from chemical composition".

Other warnings may not be out of place in relation to Part 1. Admittedly the problems of mechanism remain intractable, but no useful purpose is served by the uncritical reiteration of immature or untenable hypotheses. Jaggar's conception of the mechanism responsible for the Hawaiian cycle of activity might be of value if it were intelligibly expressed, but on pp. 33–34 the author, like earlier writers (including Jaggar himself), merely succeeds in befogging the reader. Again, in dealing with the sources of magma on p. 46, it is unfortunate that Hobbs's naïve and unacceptable assumption that local relief of pressure leads to the fusion of sediments should be cited, especially as attention is directed later on to the necessity for changes of composition by introduction of emanations from the depths.

Part 2 is concerned with less controversial topics and is an invaluable storehouse of information, admirably classified and discussed, and so thoroughly up to date that the new Mexican volcano, Paricutin, and the 1944 eruption of Vesuvius both receive appropriate mention. The chapters deal in turn with basaltic domes and cones; lava plateaux and plains; lava fields and their minor relief forms, including lava surfaces, fire fountains and their effects, bombs and spatter cones; coulees (the thick tongue-like convex flows of viscid non-basaltic lavas), tholoids (spreading cumulo-domes exuded in and over craters) and plug domes of piston-like protrusion; *nuée ardentes*, ash showers and ignimbrite sheets (a chapter that deserves special commendation); ash-built and stratified cones, with a good account of lahars of various kinds; maars and meteor craters; submarine eruptions and pillow lavas; craters, calderas, volcano-tectonic depressions (for example, that of Lake Toba) and volcanic lakes; the dissection of basalt and ignimbrite plateaux; and finally the erosion of volcanic mountains. In this last chapter welcome features are the accounts of erosion calderas and the planeze stage of dissection, a *planeze* being a dwindling sector of the initial constructional surface, surviving for a time between deeply eroded consequent valleys. The section on volcanic skeletons is, however, disappointingly brief. The collection and correlation of successive members of denudation series is a long-overdue task which Prof. Cotton is well equipped to undertake successfully. In particular it should be possible to trace ring structures from the surface manifestations developed on volcanoes such as Kilauea, Mauna Kea and Niuafo'ou, down to the ring-dykes and cone-sheets revealed at the roots of old volcanic centres, as in Mull. As it is, ring structures receive scant attention; and in Fig. 7 what are obviously cone-sheets are wrongly described as ring-dykes.

Such criticism as is offered above is meant to be helpful in the preparation of later editions, for the book as a whole is so good that it should soon progress from youth to maturity. It will be welcomed and appreciated by a wide circle of readers—for who is not interested in volcanoes ?—and more especially because the author, apart from his own valuable contributions, has made readily available, with full references, the scattered results of such active vulcanologists as Jaggar, Perret, Stearns and Howel Williams. Apart from the price, the book shows no signs of being a war-time production, but is attractively printed and profusely illustrated on good-quality glossy paper. Author and publisher alike are to be warmly congratulated on their combined success in the fields of scientific exposition and craftsmanship.

ARTHUR HOLMES.

CHILD GUIDANCE GROWS UP

An Introduction to Child Guidance

By W. Mary Burbury, Edna M. Balint and Bridget J. Yapp. Pp. viii+200. (London: Macmillan and Co., Ltd., 1945.) 7*s*. 6*d*. net.

VERY little has been published in Great Britain on the work of child guidance clinics, and ignorance on the subject is widespread. It is therefore perhaps ungenerous to criticize the authors of this small book for attempting to cover too wide a field or to address too wide an audience. The fact remains that many aspects of the work have received but scant reference, and the authors' hope to meet the needs of "all those who are actively concerned with the problems of children and young people, whether as members of education or youth committees, as magistrates, probation officers, teachers, doctors or social workers . . . and . . . also be found useful by students intending to work in child guidance clinics, as well as by those studying education, social science, psychological medicine or pèdiatrics" is too ambitious. While child guidance as a team approach to the problems of childhood strictly emanated from the United States, when the demonstration clinic was founded in London with Commonwealth Fund monies in 1928, Prof. Cyril Burt had been doing work on similar lines since 1909. Before the East London Child Guidance Clinic was opened in 1927 a pioneer group of medical men at the Tavistock Clinic, some of whom later became directors of the early clinics, dealt with more than five hundred children, assisted by a social worker who was one of the first to train in the United States and qualify as psychiatric social worker. Since that time child guidance in Great Britain has developed its own essentially British characteristics, and as every young movement needs to be jealous of its reputation and avoid inviting deserved opposition, one must needs be critical of matters that might otherwise be passed over as details.

Some duplication and contradiction is inevitable in any symposium, but slightly more careful editing might have prevented the introduction of technical terms before their description or definition. The term "intelligence quotient" is introduced in Chapters 3 and 6, and the reader has to wait until Chapter 8 before finding any explanation. Similarly, in one chapter the suggestion is made that maladjustments of foster children could be avoided only if there were panels of specially selected homes, but no mention is made of the Foster Home Register until nearly a hundred pages further on. I think one might also question undesirable jargon such as "neurotic reasons" in relation to adoptive parents, "dreaded rival" as a description of a boy's attitude to his father, "supernormal" for intelligence above the average, and the reference to "rationalisations more or less unconscious". The use of this kind of language justifies the criticisms on the part of the layman to which Dr. Burbury refers in her introduction. Keeping the general reader in mind, debatable statements might well be omitted, such as that foster mothers undertake the care of children primarily as a congenial method of adding to their income, that the mother whose brass knocker is always the brightest in the street and whose windows gleam in front of spotless white curtains is an obsessional neurotic who can never rest, or that the child who lies awake for long hours is commonly masturbating. Such situations may and do occur, but it would be a pity if the reader were tempted to generalize and the captious critic provoked to caustic comment.

Perhaps the best part of the book is the last, dealing with the methods of examination and treatment, although psychotherapy of children is a particularly difficult subject to describe clearly to the outsider. Chapters 7 and 12, on the job of the psychiatric social worker, are especially well done, and Chapter 14 on future trends is thoughtful and stimulating although it touches only on the fringes of what could and should be done in the preventive fields. Child guidance stands for one of the earliest approaches to children's problems along the lines of social medicine, investigating and attempting to correct the causes of maladjustment of the individual to his environment. It is "concerned primarily with unsatisfied inner needs rather than with physical or intellectual difficulties", but such dissatisfaction gives rise to many types of symptom, and treatment stands as much for environmental change as individual therapy. The scales are carefully balanced between the rights of the individual and the demands of society, and there is reason to hope that the principles that underlie child guidance may expand far outside the clinics into the schools and homes of the people.

It may be hoped that this small work will have a reception that will encourage its authors and others working in the same field to write further and more comprehensive books on the subject.

ALAN MABERLY.

CLIMATOLOGY FOR METEOROLOGISTS

Climatology

By Prof. Bernhard Haurwitz and Prof. James M. Austin. Pp. xi+410+17 plates. (New York: McGraw-Hill Book Co., Inc., 1944.) 4.50 dollars.

THE authors of this book set out to provide an introduction to climatology for the student of meteorology. Since the public which they aim at interesting is meteorologically educated, the authors are free to use meteorological terms, and they have made use of this freedom to write a book on climatology which is rather different from any other book on this subject. In the course of the last two decades, synoptic meteorology has been steadily progressing, mainly along the lines of analysis of weather charts developed at Bergen in Norway. Weather is now interpreted in terms of air masses and of the fronts which separate them, with an enormous gain in understanding of the physical processes underlying the changes of weather with place and time.

Climatology may be defined, perhaps a little crudely, as the time-integral of weather, and so there should be a close correlation between the interpretation of climatic data and the interpretation of the facts depicted on the synoptic chart over a selected interval of time. Hitherto this correlation has not been very obvious in the text-books of climatology.

In the book under review, Profs. Haurwitz and Austin have broken new ground in endeavouring to interpret climatological data in terms of air-masses, and their book is a definite step forward in the development of climatology. The book is in two parts, the first dealing with general climatology, the second with regional climatology. Under the heading of general climatology we find a discussion of solar radiation and heat balance of the atmosphere, temperature, wind and pressure, hydrometeors, air masses, fronts, cyclones and anticyclones. The discussion of these topics is of necessity brief, but is perhaps ample for the purpose of the later sections of the book. Many of the diagrams used have not hitherto appeared in text-books, and the authors are to be congratulated on their effective choice of diagrams for illustrating these early chapters. In the subsequent chapters of the first part of the book, the authors describe in some detail Köppen's classification of climates, in the form which this classification finally took (Köppen-Geiger, "Handbuch der Klimatologie", vol. 1C). This is the classification which the authors adopt as the basis of the second part of the book. But between the chapters describing the types of climate and those dealing with regional climatology is interposed a chapter on micro-climatology, which seems curiously aloof from the rest of the book. What is in general called micro-climatology is not in reality climatology, and could more logically be called micro-meteorology. The inclusion of a chapter on the subject in the middle of the present book appears to the present reviewer a tactical error, since it is a barrier to the smooth development of the plan of the book.

The second part of the book deals with regional climatology of the globe, dividing the globe into eight areas, and devoting one chapter to each area. In each chapter are discussed briefly the physical features, the mean distribution of pressure and wind, ocean currents, the prevalent air-masses, fronts, cyclones and anticyclones, and the climatic types occurring within the area. The amount of information given under each heading varies from area to area. For example, the accurate description of air masses over most of Africa is not possible in the absence of adequate upper air data, and the brevity of the three chapters dealing with Australia and New Zealand, with arctic and antarctic, and with oceanic regions, is to be ascribed to the inadequacy of certain types of data from a very large part of the globe.

Each of the eight chapters contains tables of frequencies of wind directions in January and July for a selection of stations, and tables of mean temperature, precipitation, and cloudiness in January, April, July and October, for a number of selected stations. The times of observation are not stated.

A revolution in the method of presentation c climatological data appears to be inevitable, but muc intense work will have to be done before this revolution is achieved. The authors of the present boo have made a beginning, and it is likely that shortl there will be much fuller meteorological dat available for nearly the whole globe, the discussion of which will make it possible to give fulle treatment of many of the topics they have discussed.

The book under review is to be recommended t all who take an intelligent interest in climatolog be they meteorologists or geographers.

D. BRUNT.

THE RACE PROBLEM IN SOUTH AMERICA

El Indoamericanismo y el Problema Racial en la Américas

Por Prof. Dr. Alejandro Lipschutz. Segunda edicion Pp. 501+32 plates. (Santiago: Editorial Nascimento, 1944.) n.p.

PROF. LIPSCHUTZ explains that what he means by Indo-americanism is the vindication of the economic and cultural rights of the masses of Indians and mestizos of America, who have been up to the present "disinherited". His book is a plea for an "Indo-american resurrection", which, it may be noted, has already been partly brought about in Mexico. He attacks what he calls "racial hypocrisy", that is, the justification of the inferior social position in which certain portions of the population are kept, by the excuse that those of American Indian or African Negro blood are racially inferior to the descendants of Europeans. A considerable part of the book is a discussion of the supposed biological inferiority and superiority of different races of mankind, and the degeneration that is popularly supposed to result from racial miscegenation. He deals not only with the American Indians but also with the African Negro, and makes use of the abundant anthropological literature that now exists on this subject.

The racial problem, as the author says, is not really a biological but a social problem, and it presents itself in different forms in different countries. What Prof. Lipschutz is concerned with is that the descendants of the conquered Indian tribes and of the African slaves constitute what may be called a deprived class condemned by the present social system to occupy, economically and culturally, an inferior position. This, he thinks, must be remedied by a widespread social reform if the Spanish American republics are to survive as independent national entities by the side of the United States within a united American continent.

The author thinks that the future of the whole American continent depends on the racial problem of North America. He recognizes the gravity of the problem of racial discrimination against the Negroes of the United States, but finds some grounds for optimism in the fact that sixty or seventy years ago the American Indians were in that country regarded as an essentially inferior race and that the attitude towards them has now greatly changed.

A. R. RADCLIFFE-BROWN.

THE SECRETION OF MILK*

By Prof. H. D. KAY, O.B.E., F.R.S.

National Institute for Research in Dairying, Shinfield

OUR knowledge of the cytology of milk secretion—what structures in the large cells lining the lveoli of the mammary gland are concerned with the formation of the various milk constituents—is meagre. There is no doubt that all the milk contituents are secreted by the same type of cell; there re not separate cells secreting fat, others secreting casein, others secreting salts and so on. It is now sually agreed also that the milk-secreting cells are airly permanent structures; that is, that milk does not originate from the breakdown and dissolution of complete cells which are renewed again and again from the basement membrane. This would entail far more mitosis and repair in cell structure than can be seen in the actual functioning gland, and would probably entail the presence in milk of fairly large amounts of substances derived from the cell nuclei, such as nucleoproteins or breakdown products of hese proteins which are, in fact, only present in traces in milk. What appears to be the case is that apart from occasional breakdown and repair, he alveolar cells maintain their nuclei and general integrity throughout a large part of a lactation period.

The day's work of one of these cubical cells entails the following cycle of operations. It begins as a rather short squat cell with the nucleus in the middle. Granules or globules, some of which stain with fat-soluble dyes, then begin to appear in the part of the cell nearest the alveolar space. The cell begins to increase in length and size, the nucleus remaining fairly close to the basement membrane. The secretory products soon fill the whole of one end of the tall, distended cell. These products, and possibly a small part of the cytoplasm of the cell itself, are now extruded into the lumen of the alveolus as milk, following which discharge the cell returns to its original squat shape. This whole process is repeated several times until the alveolar spaces become distended with secreted milk and the whole of the rest of the storage space in the gland is also occupied, whereupon further secretion ceases. During twenty-four hours in an actively lactating cow there may be up to four or five or even more cellular cycles of operation. Milk secretion proceeds continuously throughout the major part of the twenty-four hours, possibly interrupted during the actual milking process.

Though the cells are tiny compared with, say, the size of an *Amœba*, there is plenty of room inside each one for a very complicated structure, a part of which has been revealed by ordinary microscope and histological methods. The development of the electron microscope gives an increased hope of further accurate knowledge of the lay-out of these tiny factories, but it will probably be a long time before their detailed structure, the mode of action of the enzymic systems which are known to exist in these cells, and the associated biochemical changes, many of which have already been observed, and which I now propose to discuss, have been completely co-ordinated.

The Biochemistry of Milk Synthesis

It is clear that the basic materials from which milk is made, as well as those needed for producing the energy for milk secretion, must be brought to the mammary gland by the circulating blood. The main problems can be stated in the following general terms: (1) What are the chemical materials in this blood which are used for (*a*) the manufacture by the milk-secreting cells of the principal milk constituents, (*b*) as a source of energy for the work done by the active gland? (2) How is this manufacture actually brought about in these cells? In the cow, two mammary arteries, one of which serves the front and rear quarters on each side of the udder, provide the whole of the incoming blood. The arteries rapidly sub-divide to form arterioles and capillaries in close touch with the alveolar cells. A sample of blood taken from any part of the arterial system will contain all the materials either for milk manufacture or to meet the energy needs of the udder.

Three constituents of milk (Table 1), at least, are not present as such in the circulating blood, namely, milk fat, casein and lactose. Two at least of these, namely, lactose and casein, are produced nowhere in Nature but in the cells of the mammary gland.

TABLE 1. RELATION BETWEEN THE CONSTITUENTS OF COWS' BLOOD AND THOSE OF COWS' MILK.

(Quantities shown in mgm. per 100 ml.).

Constituent	Blood plasma	Milk	Ratio (approx.) blood : milk
Casein	Nil	2800–3000	—
Lactalbumin	Nil	350–450	—
Globulin	1200–2000	50–150	1 : 0·1
Lactose	Nil	4600–4900	Blood glucose : milk lactose as 1 : 80
Glucose	45–60	Traces	
Fat (as fatty acids)	150–300	3000–4000	1 : 15
Ca (total)	10–12	120–140	1 : 12.
K	16–20	120–180	1 : 9
Cl	270–300	90–120	1 : 0·4
Inorganic P	4–6	60–80	1 : 15
Total acid-soluble P	4·2–6·5	65–90	1 : 15
Lipin P	5–7	4–12	1 : 1 5
Urea	30–40	30–40	?1 : 1

Other constituents of milk are present either in much larger or much smaller concentrations than in blood. A very few, such as urea, which is freely diffusable through most of the tissues of the body, are present in equal concentration in both blood and milk. Whereas the inorganic salts of milk must clearly come from the inorganic salts of the blood plasma (for example, calcium, potassium and chlorine) it is by no means necessary that the organic constituents of the milk are derived from the more or less obvious precursors in the blood, for example, milk sugar from blood sugar.

As regards venous drainage, the system of blood vessels is more complicated. There are actually three routes by which venous blood leaves the gland, the main one being the subcutaneous abdominal vein which goes forward from the gland just below the skin (the so-called milk vein) and enters the abdomen through a small hole—the 'milk well'—in the abdominal wall. There are considerable anastomoses between the various veins, so that a sample of blood taken from the 'milk vein' gives a fair picture of the composition of the blood leaving the gland.

By comparing, therefore, the composition of the arterial blood reaching the secreting gland with that of the venous blood leaving it, one should, it would seem, be able to determine what blood constituents are being used by the gland.

---

* From a Royal Institution discourse delivered on May 18.

The veins are not, however, the only channel through which circulating fluid leaves the mammary gland. There is also, as in most other active tissues of the body, a well-developed lymph drainage system, as extensive as the venous system. The lymphatic system drains the tissue spaces, whence the fluid which originates from the circulating blood is slowly but continuously removed, passed through lymph nodes (there is a particularly large lymph node, up to some 10 cm. long, on the top of the udder on each side) and by a long lymphatic channel furnished, like the venous system, with valves, and returned to the circulating blood through the so-called thoracic duct, which pours a slow stream of lymph into the venous blood of the anterior vena cava, just before the blood reaches the heart. The rate of lymph flow from the mammary gland is undoubtedly very much less than that of the venous blood flow, but in what quantitative relationship the two stand is at present a matter of guesswork. Nevertheless, any balance sheet which might otherwise be drawn up over any given period of secretion, say twenty-four hours, as between the quantity and constituents of blood entering the gland on one side, and the blood plus milk leaving the gland on the other, is complicated by this small but quantitatively unassessed expenditure from the arterial blood which does not appear either in the venous blood or in the milk itself.

The first whole-hearted attempts to discover the nature of the milk precursors gave misleading results. The particular method used was to analyse samples, taken simultaneously, of mammary venous blood and of jugular venous blood. Satisfactory methods for obtaining true arterial blood had not then been worked out, and it was assumed that the easily obtainable jugular blood, draining the head, which was considered to be a relatively inactive part of the organism, in the cow at any rate, would be fairly close in composition to true arterial blood.

This was clearly shown, by later workers at the Hannah Research Institute, not to be the case, so that one at least of the main conclusions drawn from the first experiments, that butter fat in milk was mainly derived from the phosphorized fats of the blood, was incorrect.

Most of the recent work, that is, since about 1932, has been carried out by more reliable methods. Methods of arterial sampling without disturbance of the cow have been developed in various research centres; for example, sampling from the internal iliac artery, which can be easily approached through the rectum of the animal, or principally in goats, from a portion of the carotid artery which has in a previous minor operation been exteriorized in a loop of skin. It may be said at once that the method of obtaining the blood samples is more than half the battle. It was clearly demonstrated at the National Institute for Research in Dairying, at Shinfield, in 1934, that disturbance of the animal during sampling must be avoided, otherwise analysis of the blood samples was largely waste of time. It is not at all easy to take an arterial and venous blood sample practically simultaneously without some disturbance, though individual animals vary very greatly in their perturbability.

To get over this difficulty, two other methods have been used fairly recently: one is the use of an anæsthetic, nembutal, which removes nervous exci ment and appears not to interfere with the secreto process; the other is by, so to speak, removal of t animal altogether (a method first used, tentativel by Foà some thirty-five years ago), namely, b excising the mammary gland and perfusing the latte with as little delay as possible, either with oxygenate defibrinated blood or with oxygenated whole blo prevented from clotting with a suitable anticoagulan such as sodium citrate or heparin.

None of these methods is perfect, but each has i advantages and disadvantages. The perfusion tec nique very recently developed by Petersen, Shaw an Visscher in Minnesota is one requiring much exper mental skill. It is said that the gland can be i action within seven or eight minutes of the slaughte of the cow. By this method various blood pressur can be used, various materials can be added to th arterial blood, and blood sampling, both 'arteria and venous (a single venous exit is arranged), is easy while milk can be collected without too much diff culty. The isolated gland cannot be used too long a it is, of course, steadily deteriorating, and again th question arises as to how far the interference wit lymphatic drainage affects the findings.

The nembutal anæsthesia method, also develope in the United States during the War, is said to hav no effect on blood sugar or on the rate of mil secretion in goats, or on the energy requirements o the mammary gland.

An entirely different method for the study o mammary gland metabolism is the incubation, i well-oxygenated salt solutions, of fresh slices o mammary tissue with various possible precursors o the milk constituents.

Still another method is by the use of radioactive elements such as radioactive phosphorus or calcium or of 'heavy' elements such as deuterium ('heavy hydrogen') or 'heavy' nitrogen, which, suitably combined, can be given to a lactating animal by mouth or intravenously, and followed through into the milk by appropriate physical means. This very promising method has so far been used only in a preliminary way, though Hevesy and Aten in Holland, in 1938, made a few useful observations using radioactive phosphorus.

Chemical Changes from Arterial to Venous Blood

Blood sugar. These changes are the largest in actual percentage; there is a fall varying from 10 to 25 or even 30 per cent of the total arterial blood sugar.

Blood fat. There is a fall of about 3–5 per cent in the neutral fat of the blood in passing through the gland.

Lactic acid. The position here is not yet clear. Some earlier experimenters claimed that fairly large amounts of blood lactic acid disappear while going through the mammary gland. More recent work shows little change with normal, unanæsthetized animals, but there appears to be a slight uptake by anæsthetized animals in the first twenty minutes of anæsthesia, but not, it seems, later. It is an open question whether lactic acid is or is not one of the blood constituents normally used by the secreting cells.

β-Hydroxybutyric acid. This substance, which occurs in normal cow's blood in appreciable quantities, and in animals in 'ketosis' in much larger amounts, is taken up by the mammary gland in iantities which appear to vary with the concentration in the blood.

Globulin. Apparently an appreciable quantity of asma globulin, but no albumin, leaves the blood in aversing the mammary gland. The globulin which mainly involved is a glycoprotein, the molecule of hich contains some 9 per cent of a sugar complex ntaining galactose, mannose and glucosamine. here is some evidence that plasma albumin is tually greater in mammary venous blood than in terial blood.

Amino-acids. Small quantities of uncombined nino-acids appear to leave the arterial blood, and ere is a suggestion that slightly more urea nitrogen present in mammary venous blood than arterial ood.

Inorganic phosphorus. There is a drop of about -7 per cent in the amount of inorganic phosphorus in blood plasma in passing through the land.

Calcium. A fall takes place of about 2·5 per cent the amount of calcium in the arterial blood.

Since the milk contains relatively large quantities f end-products, of which several of the materials ist mentioned must be the precursors, it is obvious hat, since there is such a small quantity of precursor emoved from unit volume of blood, the rate of lood-flow through the gland must be very high (see elow).

Mammary Gland Slices

Grant, working in Great Britain, found some years go that lactose was formed when mammary gland lices were incubated in oxygenated physiological alt solutions containing glucose, but not, apparently, f fructose, mannose, galactose or various sugar-hosphoric acid esters were used. Some of these indings were later called into question, but very ecent work of Knodt and Petersen has confirmed that lactose is formed when mammary slices are ncubated with glucose, and also with glucose plus actic acid, maltose and glycogen. It is not perhaps surprising that the last two should give positive results, since both will presumably be hydrolysed to glucose by enzymes present in mammary gland tissue. β-Hydroxybutyric acid disappeared when incubated with mammary slices, the rate depending on the amount of the acid present.

Perfusion of Excised Mammary Gland

It has been shown that tissue glycogen is increased by perfusion of the excised mammary gland with blood containing added quantities of glucose, but increased blood glucose caused no significant change in the amount of lactose secreted in a six-hour period. It is very likely that, as in other tissues, glycogen can be synthesized from various normal blood constituents by the mammary cells, and later hydrolysed again to form glucose and, through glucose, lactose. Normal mammary tissue contains about 0·2 per cent of glycogen, according to American findings.

Further sidelights on the biochemistry of milk secretion are thrown by the study of the composition of milk when the secreting tissue is infected by *Streptococcus agalactiæ*, which may persist in the gland for long periods without too seriously inhibiting the flow of milk.

In the infection known as streptococcal mastitis, the secreting cells are physiologically abnormal in that instead of true milk, a fluid is secreted in which the characteristic milk constituents lactose, casein and fat and the less characteristic but very important constituent vitamin A are diminished. There is an increase in globulin and a large increase in chloride. Davies believed that mastitis milk could be regarded as ordinary milk containing larger or smaller proportions of what he called "an isotonic diluent" approximating in composition to blood plasma, with its relatively high proportion of globulin and sodium chloride. A varying proportion of udder tissue is, in effect, in a catarrhal condition and forms an ineffective barrier against this leakage. This view has recently received some support from the finding that while in the blood plasma of a cow receiving green fodder carotene is high, in normal milk the carotene content is only 3 per cent of that in blood, but in mastitis milk (even say from one infected quarter of a cow the other three quarters of which may be still normal) the carotene may be as high as 20 per cent or even more of the blood level. Vitamin A, on the other hand, is lower in blood plasma than in milk—it is not yet certain whether the udder cells concentrate the vitamin A of the plasma or actually synthesize it from blood carotene—but in mastitis milk it is, like the fat, lower than in normal milk.

Any connected account of the processes by which milk is made in the udder must provide an explanation of the interesting carotene-vitamin A-butter fat relationships in milk. Both carotene and vitamin A are present in milk in solution in the fat globules; but it has been shown quite recently that whereas the vitamin A-butter fat ratio is more or less independent of the size of the fat globule in milk, the carotene-fat ratio in the fat globule increases as the size of the globule diminishes, that is, as its relative surface area increases. This suggests that fat and vitamin A are synthesized, or perhaps one had better say assembled, by the same mechanism in the secreting cell, whereas the closely related (and also fat-soluble) carotene finds its way into milk by a different process associated in some unknown way with the *surface* of the fat globules.

All the water-soluble vitamins investigated—vitamin C, riboflavin and vitamin B_1—are considerably more concentrated in milk than in blood. Vitamin C is concentrated some eight times, riboflavin perhaps about four times, and total vitamin B_1 two or three times. All three are depressed in amount in mastitis milk, as would perhaps be expected since a function of the normal secretory cell is to take them up from the blood and concentrate them, a function which partially breaks down in the infected cell.

Energy Changes in Milk Secretion

Despite the rapid flow of blood through the mammary gland, a considerable proportion of the oxygen reaching the gland from the arterial blood is used up for combustion of one or more oxidizable substances in the tissue. Quantitatively, in some Shinfield experiments in which we were satisfied that the cows were undisturbed, the amount of oxygen used by the secreting gland was 4–5 volumes for each 100 volumes of blood, while at the same time 5–7 volumes of carbon dioxide were given out to the venous blood. The so-called respiratory quotient—volumes of carbon dioxide given out divided by volumes of oxygen used—was invariably higher than 1 in all experiments where the cows were undisturbed.

Similar findings have been made in at least two laboratories abroad, with both goats and cows; that is, in the undisturbed, normal animal, a mammary gland respiratory quotient of well above 1, usually between 1·1 and 1·3, is found.

If these findings are to be interpreted along the usual lines, it would mean that the secreting cells were synthesizing fat from carbohydrate. The American workers, who found that β-hydroxybutyric acid was being taken up from the blood by the gland, suggested that it was being partially oxidized and partially transformed into the short-chain fatty acids which occur specifically in milk fat. But it is known that the amount of blood *fat* taken up by the mammary gland is sufficient to account for all the milk fat secreted, so that this suggestion requires further evidence before it can be accepted.

Until we are fairly certain what substances are actually serving the gland as sources of energy and what blood precursors are transformed into milk constituents, exact knowledge of the energy changes in the gland will not be forthcoming, and it is probably idle to make any thermodynamic speculations at present.

Rate of Blood Flow through the Secreting Udder

One of the earliest estimates of the number of volumes of blood required, on the average, to produce one volume of milk, was made by the Shinfield workers in 1935, by comparing the fall in fatty acid, inorganic phosphorus and sugar between arterial and mammary venous blood. It was considered that probably between 400 and 500 volumes of blood must circulate through the udder to produce one volume of milk. This figure was little more than a guided guess, and it was pointed out at the time that implicit in this conclusion was the view that the lymphatic drainage of the udder could be regarded for the purpose of calculation as negligible—a likely assumption, but little more than an assumption. Afterwards, by use of a 'stromuhr' or volume-meter actually inserted in the circulation, Graham found that the blood flow was only about half our estimate. Still later findings of Shaw and others, who have used a rather different method of assessment, namely, by determining the amount of total calcium and total phosphorus taken, on the average, out of unit volume of blood by the udder, and the amount of the same materials in the milk secreted by the same animal during twenty-four hours, point again towards our original estimate of 400–500 volumes. Their average figure is given as 494 volumes of blood for each volume of milk—an average finding, of course, the lowest figure being 331 volumes for total phosphorus in one experiment and the highest 650 in one experiment for total calcium.

The results summarized in the accompanying table are probably not very far from the truth, though the experimental errors in the second column are quite appreciable, and also the efficiency of uptake of any blood precursor by the mammary cells will, like the efficiency of any other physiological process, undoubtedly vary from one cow to another and in the same cow at different stages in the lactation period and even at different times on the same day. It may nevertheless be concluded that, with a reasonably good cow at the peak of her lactation, giving say four gallons of milk a day, approximately nine tons of blood, say eighteen times her own weight, will pass through the udder each day.

TABLE 2. MAMMARY GLAND BALANCE. SUMMARY.

(From Shaw, Powell and Knodt, 1942.)

Blood precursor	Gland utilization per litre of blood (gm.)	Suggested end product				Ratio of blood volume to milk volume
		Milk substance	24 hr. production (gm.)	Blood required (litres)	Milk produced (litres)	
Calcium	0·0021	Calcium	22·52	10,931	19·40	563 : 1
Phosphorus	0·0021	Phosphorus	17·61	8,246	,,	425 : 1
Calcium +phosphorus	0·0042	Calcium +phosphorus	40·13	9,588	,,	494 . 1
Neutral fat	0·0684	Fat	707·5	10,817	,,	532 : 1
Glucose	0·1122	Lactose	985·5	9,070	,,	468 . 1

Precursors of Milk Constituents

To sum up, our present knowledge of th precursors of the main milk constituents is a follows :

Milk fat. This is almost certainly derived from the neutral fat of the blood. The short-chain fatt acids in milk fat are probably derived, as Hilditc first suggested, from the breakdown of some of th long-chain fatty acids in the blood fat, though th recent findings of Barcroft and his co-workers tha the ruminant is able to take up short-chain fatty acids direct from the rumen and that these ma circulate in the blood has to be borne in mind.

Lactose. This is almost certainly derived from the glucose of the circulating blood, though the latter sugar may pass, in part in any event, through intermediate stages such as lactic acid or even glycogen in the gland cells before being transformed into the lactose. Part of the lactose may come from the sugar-containing globulin which is taken up by the active gland cells from the blood.

Casein and lactalbumin. There is little doubt that amino-acids in the circulating blood contribute at least a little toward the synthesis of one or both of these proteins by the gland cells. Doubtless a major portion is contributed by the blood globulin which is now known to be taken up by the secreting tissue. Using radioactive phosphorus, it has been shown that the inorganic phosphate of the circulating blood provides the phosphorus organically combined in the casein molecule. We know less about protein synthesis by the gland than about fat and carbohydrate synthesis.

Energy. We know next to nothing as to what carbon compound is burnt in the mammary gland to provide the energy needed for synthesis of the milk constituents. It may be glucose, lactic acid, the sugar-containing moiety of the blood globulins just mentioned, or β-hydroxybutyric acid, or a part of the blood fat, or a combination of two or more of these.

In this connexion it seems more than likely that the secreting cells may be capable, like other tissues of the body, of using different materials for energy production or for milk production at different times and under different nutritional conditions. Although the secreting tissue of the mammary gland appears histologically to be simpler than that of, say, the kidney, it is clear from what has just been said that the activities of these large mammary cells are very complex. Their internal structural pattern and enzymic equipment are at present almost unknown.

CERVICO-FACIAL PIGMENTATION (MELANOSIS OF RIEHL-POIKILODERMA)*

By Dr. GEORGES GARNIER

Paris

Translator's Note. On a recent visit to Paris I was struck by the number of women suffering from diffuse pigmentation of the face. I saw my first cases in the streets and only learnt the nature of the condition when I visited the hospitals, where it is a commonplace in all dermatological clinics.

The melanosis of Riehl[1] is, to most British dermatologists, only a name, as it is a rarity in Great Britain as much in war-time as in peace. Its appearance in the War of 1914–18 and in this in starved populations seems more than mere coincidence, but the title 'war melanosis' given to the condition by Hoffmann and Habermann[2] has been challenged by Comel[3]. The condition is the subject of much discussion in France and there is great diversity of opinion as to its cause. Dietetic deficiency is not always obvious: the condition is seen in well-fed country dwellers as well as in city dwellers who have, on the whole, a very low dietetic intake. 'Nervous shock', so often invoked in conditions of unknown origin, has not been forgotten. Dr. A. Touraine, at the May meeting of the Société Française de Dermatologie et de Syphiligraphie, made a strong plea for the acceptance of the use of hair dyes as an important cause, but was just as strongly challenged by other members of the Society.

Dr. Georges Garnier's paper, which he has generously allowed me to translate, gives a well-balanced account of the various clinical and etiological aspects of cervico-facial pigmentation.

James Marshall.

THE obvious increase in incidence of cases of cervico-facial pigmentation directs attention again to this curious dermatological syndrome, which raises a series of clinical and etiological problems. Dermatologists describe the condition either under the name of melanosis of Riehl, the Viennese author who described it in 1917, or under the name of reticulate pigmentary poikiloderma of the face and neck, as described by Civatte in 1922[4]. For a certain number of authors these are two different conditions, closely related and almost completely identical histologically (Petges; Pierini and Bosq; Noguer More and Grau Barbera). For others (Civatte, Sézary), on the contrary, there is only one disease, or rather one single syndrome, in spite of the clinical differences to be described later. Until the last few years published observations have usually appeared under the title of reticulate pigmentary poikiloderma of the face and neck. More recently in France, Sézary, Jausion, Gougerot, Degos and Garnier have reported their observations under the title of melanosis of Riehl.

Whatever the term adopted, it must be recognized that it lumps together a number of features which may appear a little incongruous when one tries to detail the etiology and pathogenesis. There must first be distinguished groups where abnormal pigmentation is secondary to a pre-existing dermatosis. With R. Degos I described to the Society of Dermatologists in 1943 the case of a patient who presented clinical signs of poikiloderma (pigmentation and telangiectases) and who also had lichen planus. This dermatosis, so often productive of pigmentation, had assumed the appearance of reticulate cervico-facial melanosis. In studying earlier observations I have been struck to see how often lichen planus has been evoked or suspected in like cases, and where, in spite of a somewhat hesitant diagnosis, the publication carried the title of cervico-facial poikiloderma. There is a case described by Nomland[5] where Finnerud and Oliver do not accept the diagnosis and suspect a lichen. Similarly, Louste, Lévy-Franckel and Cailliau[6] describe a case where there were shiny papules with atrophic centres and a buccal leuco-keratosis, the condition being improved by 'Acetylarsan', a common therapeutic agent in lichen planus. In this connexion there can also be cited the observations of Gaté, Cuilleret and Bret[7], of F. Wise[8], and of Wiessenbach, Lévy-Franckel and Martineau[9]. It seems, therefore, that a certain number of cases described as reticulate pigmentary poikiloderma are in fact more or less typical cases of lichen planus and that this is a diagnosis which should be suspected more frequently.

Whatever they may be, these cervico-facial pigmentations present the following clinical picture: the patient, usually a woman, sees the progressive development of a pigmentation composed at first of isolated spots, soon becoming confluent into more or less extended patches on the forehead, temples, cheeks and lower eyelids and descending along the jaws to reach the sides and sometimes the nape of the neck. Usually the pigmentation stops one or two centimetres from the hair margin. In some cases an extension to the forearms has been described. The colour of the pigmentation varies from a deep greyish-brown through chocolate, sometimes reaching violet. It is disposed in irregular plaques with islands where the skin has kept its normal colour (notably around the pilo-sebaceous orifices), producing a reticulate aspect which sometimes suggests poikiloderma. However, there is usually lacking a symptom which is part of the classical triad of poikiloderma, namely, telangiectiasis. This is not mentioned by Riehl nor in most of the observations recently published in France under this name. Atrophy also may be lacking or may exist only in a most discrete fashion on certain regions, notably the temples. It must be admitted, however, that atrophy is not always easy to recognize clinically, and might be more frequently found on histological examination.

Such is the appearance in most cases of war melanosis of the type described by Riehl, and which corresponds to those recently observed. In the observations of Civatte and certain others there have been noted also the association of telangiectiases with reticulate pigmentation. Melanosis may extend to the arms and forearms, and certain authors have even noted patches of pigmentation on the buccal mucosa. Finally, one may see on certain patients special lesions, punctate blackish hyperkeratotic papules on the dorsa of the fingers, on the hands, and even on the forearms, resembling, when most marked, a follicular keratosis or pityriasis rubra pilaris, or even giving the appearance of oil acne. It is a question then of people working with tar derivatives, or with oils, the lesions being at maximum in the toxic lichenoid melanoderma of Hoffmann and Habermann in which hæmorrhagic bullae have been noted, and where there is a professional factor (tar workers).

---

* First published in *La Presse Médicale*, 30, 435 (August 14, 1943). Translated by Dr. James Marshall.

It is necessary in the consideration of the etiology of the condition to distinguish external and internal factors.

External Factors

Light has been invoked as a cause by numerous authors. It must be admitted that the localization of the melanosis on uncovered regions obliges us to take note of this. Light may act directly or in conjunction with a photo-sensitizing substance. In the case of direct action, the influence of light can be manifested by the appearance of an erythema which, more or less intense, sometimes precedes the appearance of pigmentation. Such was the case of one of the patients I recently described. This was a well-nourished woman of seventy years, in whom the melanoderma appeared after exposure to July sunshine which had caused intense redness of the face.

In other cases the action of light is exercised indirectly through the intermediary of a photo-sensitizing substance, which may act locally on the skin or be absorbed by the organism. The most important examples of the first type are tar and its derivatives, in which is found a fluorescent substance that is particularly photo-dynamic, acridine (Hoffmann). In the second type the sensitivity results from the respiratory or digestive absorption of the noxious substances (Kismeyer, Meyrovosky).

Other authors have blamed contact with lubricating oils (Thibierge); coal, in the case of an engine driver (Lortat-Jacob, Legrain and Cléret); creosote in railway sleepers, in the case of a platelayer (Hudelo, Cailliau, and Mornet); certain dye substances (Gougerot and Weil); cresyl (Garnier); and certain paints (Garnier). In a patient I saw recently I suspected hair dye as the cause. The dye involved was a substance of the chrysoidine type which gave no immediate cutaneous reaction but which sensitized the skin to ultra-violet light, as was shown by test. In this patient were associated both internal and external factors as, besides the action of the dye, there was a high porphyrinuria which further explained the photo-sensitization.

Internal Factors

These are many. Some cases show signs of visceral disease. Alcoholic liver damage was noted in numerous observations (Civatte, Lortat-Jacob, Sézary), and this would explain a porphyrinuria.

Other cases show endocrine disorders, notably ovarian (Civatte) and suprarenal (Sézary, Navarro-Martin and Aguilera). The role of the latter in pigmentogenesis is well known. The influence of the suprarenal must be investigated even if it does not appear to be the cause at first sight. I published in 1938[10] an observation on a woman with a typical melanosis of Riehl where cresyl might have been the cause, but who, a year later, died of Addison's disease. Sometimes it is the pituitary which is incriminated, but the influence of this gland is more difficult to decide.

We arrive finally at the elementary factors which, from the start, have been evoked by Riehl and which predominate in the pathogenesis of melanosis. It is striking to note that the first cases were observed in Central Europe, where the dietetic restrictions were particularly severe during the War of 1914–18, and that similar cases are now arising among our starved populations. Riehl at first suspected as the cause certain *ersatz* substances which were used in war-time bread (flour made from various leguminous plants). Hoffmann incriminated maize, others su pected margarine (Baschk) and barley (Kerl). A these products were capable of producing a phot sensitization analogous to that produced in pellag and in certain animal diseases (fagopyrism and tr foliosis). Avitaminoses must also be mentione notably deficiency of vitamin P.P. which is involve in the metabolism of the porphyrins. The role c porphyrinuria in the pathogenesis of the melanosis c Riehl is not considered important by some author (Petges, Jausion), while others take the opposit view. The quantity of urinary porphyrins, which i normally from twenty to forty gammas per litre, ma attain two hundred and eighty gammas (Garnier) and even sixteen hundred gammas in a case describe by Degos and Carrot[11] in a prisoner-of-war whos pigmentation improved after his return to mor normal diet.

Vitamin C deficiency may also be a cause. Moravit has suggested that it has a part in the pigmentatior of Addison's disease. One of my patients presented a marked diminution of urinary ascorbic acid and was much improved after administration of vitamin C.

To summarize, it is necessary to consider cervico-facial melanosis as a syndrome which can arise from different causes. Some are external, for example, (1) light; (2) tar products acting as photo-sensitizers; (3) direct action of toxic products on the skin. Others are internal, for example, (1) visceral and endocrine deficiencies; (2) disorders of porphyrin metabolism; (3) avitaminoses. The pathogenesis of the cervico-facial pigmentations is most complex, as all these causes may act alone or, oftener, in association.

From the clinical point of view it is difficult to classify the cervico-facial melanosis syndrome. Abroad, numerous authors (Kinnear, Noguer More, Grau Barbera, Pierini and Bosq) distinguish: (1) Melanosis of Riehl, a pure pigmentation in which is lacking clinical evidence of telangiectases and atrophy and in which contact with external factors is a part of the history. (The toxic lichenoid melanoderma of Hoffmann is classed only as a particularly intense variety in which professional causes preponderate.) (2) The reticulate pigmentary cervico-facial poikiloderma of Civatte in which the melanosis is associated with telangiectases and atrophy. This variety is classed as a localized form of the poikiloderma of the type described by Petges and Jacoby. Internal factors, notably endocrine, predominate, and external causes blamed in the melanosis of Riehl are not found.

In reality, these differentiations are more academic than real. Many of the clinical characteristics invoked to distinguish these two groups are disputable. The pathogenic factors, external in the melanosis of Riehl, internal in the cervical-facial poikiloderma of Civatte, are alike insufficient to draw exact limits. We have seen that Riehl himself suggested a dietetic cause for the melanosis he described, and is it not possible in a cervico-facial poikiloderma lacking external causes at least to admit the possibility of light being a factor and adding its action to visceral and endocrine disorders? On the other hand, it seems to me necessary to set aside a group of cervico-facial melanoses in which the pigmentation is secondary to a pre-existing dermatosis, often undiagnosed, in particular, lichen planus.

Treatment

By its slow persistent evolution on the face and neck it constitutes for patients an æsthetic trauma which, in certain women, can lead to a veritable obsession. It is important, therefore, to apply treatment which, though it cannot be rapidly effective, will at least retard the extension of the disease and hasten its regression. Locally, the bleaching lotions normally used are without effect. It is necessary to avoid injury by light and to prescribe an anti-actinic cream containing 6 per cent of menthyl salicylate. The handling of noxious substances, tar and its derivatives, dyestuffs or paints must be stopped. In certain cases one must compensate endocrine deficiencies (ovary and suprarenal particularly). Finally, one must counteract the various vitamin deficiencies, in particular of vitamin P.P. and vitamin C. It is necessary to give a high dosage of nicotinamide (0·6 gm. per day at least, by mouth) and to add, if deficiency of vitamin C is suspected or proved, ascorbic acid (0·3 gm. per day at least).

NEWS and VIEWS

Prof. L. Bairstow, C.B.E., F.R.S.

THE retirement of Prof. L. Bairstow from the post of Zaharoff professor of aeronautics in the University of London marks the departure of a pioneer from the scientific side of aviation. Bairstow began his work on aerodynamics so long ago as 1909. He was then on the scientific staff of the Engineering Department of the National Physical Laboratory, and when it was decided to undertake aerodynamic research in the Laboratory, he was charged with the formation of a small group of workers and the carrying out of research under the general control of the Advisory Committee for Aeronautics. He very quickly justified the confidence placed in him and began to lay the foundations of the new science. Seeing at once the fundamental importance to aerodynamics of the theory of dynamic similarity, he initiated experiments in air and water to prove its truth to the unbelieving. By 1911, he and his collaborators had made a number of investigations on wind tunnel design and had succeeded in producing what was the first really satisfactory wind tunnel in Britain. About the same time he was studying the theory of the stability of aeroplanes, as laid down by Bryan, which he extended very greatly as time went on and generalized to cover all six degrees of freedom. He employed the wind tunnel to measure aerodynamic stability derivatives, and by using the values so obtained in the light of the theory, he produced the first clear account of the disturbed motions of aircraft, and established the fundamental basis of all later developments in this field. He even traced the motion of an aeroplane as it flew through a prescribed gust. An example of his experimental versatility was an attempt to investigate the motions of airships by tests on models about six inches long in a water stream flowing at a few inches a second! He was responsible for the first investigation in Britain on the subject of flutter, and he contributed much to the knowledge of practical flying by his investigations of flying accidents. The Aerodynamics Division of the National Physical Laboratory, as it exists to-day, owes Prof. Bairstow an immense debt of gratitude for the work he did in establishing it. This work was recognized in 1917 by the award of the C.B.E., and by his election to the fellowship of the Royal Society.

Prof. Bairstow was the first superintendent when aerodynamics became a separate Department of the National Physical Laboratory, but he left in June 1917 and took up duties at the Air Ministry. In 1920 he became professor of aerodynamics under Sir Richard Glazebrook, who then held the Zaharoff chair at the Imperial College, London. He succeeded to this chair in 1923 and has held it ever since, thus spending a large part of his life in guiding the destinies of students in the College where he himself had been educated. He became Dean of the Faculty of Engineering at London in 1935, and was appointed to the Senate in 1936. The excellence of his work at the University is well shown by the number of his students who to-day occupy important positions in industry and in the Government research institutions. Prof. Bairstow was also very active outside the University. He was vice-president of the Royal Aeronautical Society during 1930–34, but his greatest contribution, apart from his research and teaching, was his service on the Aeronautical Research Committee, of which he has been vice-chairman for many years, besides occupying the chair of several of its important subcommittees. His book, "Applied Aerodynamics", is almost a classic, and is by far the most comprehensive work on the subject by an Englishman. To those who have known him intimately, Bairstow has always been ready with counsel and advice, and has endeared himself to his many friends by his delightful personality and charm. Though he deserves a well-earned rest after a long life's work, it is to be hoped that he will still be able to spare a little of his time to help forward the great advance of aeronautics which the future appears to hold in store.

Museums and the Community

THE case for the museum in relation to modern educational and cultural developments is well and fairly examined in Part 1 of a 39-page pamphlet entitled "New Zealand Museums" by Dr. W. R. B. Oliver (Dominion Museum, Wellington, 1944). The subjects of research, display of exhibits, reference collections, buildings, policy and administration are fully reviewed, but those sections dealing with education are worthy, perhaps, of particular attention. In reference to adult education, Dr. Oliver writes: "The kind of information distributed through the Museum services is not limited to a few subjects such as biology, ethnology and geology. . . . Those subjects not dealt with in the exhibition galleries can be covered very effectively and thoroughly by films shown during the regular educational screenings. By means of films and authoritative lectures, the Museum can extend its province to cover the entire range of human knowledge." This is a fine conception of the work lying within the grasp of the larger museums, but its fulfilment, both in Great Britain and elsewhere, would seem to require closer co-operation between the museums, all other kinds of educational institutions, scientific and art societies, and individual specialists than has generally been the case hitherto. Only when the work of each is mutually understood and appreciated will the museum be able to establish itself fully as the link between the research worker and specialist, who continually advance our knowledge, and the ordinary men and women, who need to be kept informed of such advances.

With regard to school services an interesting development in the Dominion Museum is well worth attention. Before the War, this Museum provided regular instruction for visiting classes of schoolchildren. On each visit the children were first given a lecture—usually illustrated by a film—in the lecture hall. There then followed a lesson in the Museum. Here the children were divided into groups, each of which was under the charge and instruction of a student teacher from the training college. Six teachers at a time attended the Museum for this purpose for a period of six weeks, and in this way gained valuable experience in the use of museum material. They, themselves, were instructed by members of the Museum's professional staff, and so, ". . . the value of the museum to the community was emphasized to the students, who left the institution with sufficient knowledge of its capabilities and functions to enable them to educate their future charges in the purposeful use of the public museums". Part 2 of this valuable pamphlet deals more particularly with the present buildings, administration, equipment, finance, etc., of New Zealand museums.

Belgian Biological Publications during the War

Dr. Julian Huxley has received a letter from Prof. C. J. Van der Klaauw, of the Department of Zoology of the University of Leyden, and one of the directors of *Acta-*, *Folia-*, *Bibliographia-*, *Bibliotheca-Biotheoretica*. Prof. Van der Klaauw states that he is well, as is also his lecturer in experimental zoology, Dr. N. Tinbergen, although both of them spent some two years in a concentration camp, with about twenty of their colleagues from Leyden. After release from imprisonment, Prof. Van der Klaauw was exiled to the eastern part of Belgium. He adds that Prof. H. J. Jordan, professor of comparative physiology in the University of Utrecht, died of apoplexy during the War.

During the occupation of Belgium, vigorous efforts were made—with a considerable measure of success—to keep alive the biological journals referred to above, and to maintain their international character. Since May 1940, the last two parts of vol. 5 of *Acta Biotheoretica* have appeared. They contain a paper by a German (Frieling), three by writers in the United States (Rashevsky, Lafleur) and one by a Russian in France (Kostitzin, in French). Vol. 6 appeared in 1942, containing four papers in German (Friederichs, Hofstaetter, Kuhn, Meyer-Abich), two by a Pole (Wilzýnsky, in English and French), and one by a Dutchman (Ariëns Kappers, in English). Vol. 7 appeared in 1943 and contains three papers in German (Meyer-Abich, Friederichs, Thienemann), one by a Norwegian (Ubisch, in German), three by Dutchmen (Voûte, Raven, Pos ; two of them in French, one in English) ; two papers by a Pole (Wilzýnsky, in English). Another paper by Wilzýnsky (in English) and one by a Dutchman (Baas Becking, in English) will fill part of the next volum The series entitled *Bibliotheca Biotheoretica* start during the War. There have appeared : No. 1 (194 a paper by Prof. H. J. Jordan, in German ; No. (1942), a rather long paper in German by a Russi (Schaxel) ; No. 3 (1942), a long paper in English Dr. N. Tinbergen ; No. 4 (1944), a long paper English by two Dutchmen (Booy and Wolvekamp In the series *Bibliographia Biotheoretica* the appeared : Vol. 2 (literature 1930–34) in 1941, th last part of Vol. 3 (1935–39) in 1942, and in 1944 th first part (82 pp.) of the fourth volume (literatu 1940–44).

Prof. Van der Klaauw and his colleagues hav clearly done their best to maintain the internation scope of the periodicals produced by the Prof. D Jan Van der Hoeven-Stichting. They hope th British scientific workers will use their journals in th future.

Historical Background of Planning

In Occasional Pamphlet No. 1 issued by th Society for Freedom in Science (April 1945. 1*s*. 6*d*. under the title "Is the Progress of Science Controlle by the Material Wants of Man ?", Dr. F. Sherwoo Taylor makes a spirited attack on the main thes of a memorandum issued by the Association of Scien tific Workers in November 1943 on "The Develop ment of Science". Dr. Taylor challenges the historica arguments advanced in that memorandum in favou of the planning of science and, apart altogether fron the question whether or not those arguments ar justly inferred from true historical data, Dr. Taylor' pamphlet is to be welcomed as a corrective to an undoubted tendency to mix propaganda and history. It should stimulate clearer thinking about the development of science: science, he reminds us, is something done by people, and if it is organized at all, it is organized by people. He urges that no causes should be looked for outside the internal logic of science, until those within it have been exhausted. Listing the great discoveries of the years 1775–1800, he considers that only Watt's improvements in the steam engine, Cort's puddling of iron and Jenner's vaccination can be said to be dictated by human needs ; and similarly, while applied science workers are concerned to bring the discoveries in pure science into rapid use, the great discoveries of the last fifty years were not dictated by human needs. Simply from the point of view of causing discoveries to be made, the community must take a long-term view and encourage science to advance in its own way.

Dr. Taylor frankly challenges the practicability of planning pure science, even by men of science ; let the community plan applied science if it can, he says. If any planning or direction of funds has to be done, let the planning and direction be on the basis of the maximum increase of research directed to knowledge and irrespective of use. But while he rightly argues that to ensure the maximum of scientific research will give the maximum useful rewards to the whole world, he passes over the fact that resources are limited, that the research front is uneven and advance in some fields is retarded by neglect elsewhere. So, too, while he is right to urge the reading of the works of the great men of science instead of modern books advancing not wholly uncoloured views about them—advice which might well be heeded by many scientific workers, apart from the public, who would thus be better able to understand the nature of the scientific man and his methods—he is just a little too sweeping in his condemnation of the reading list provided in the A.S.W. pamphlet, and he might have strengthened his case by a reference to the "Source Books in the History of Sciences" published by the McGraw-Hill Book Co., which within their limits overcome the difficulty of accessibility to which Dr. Taylor refers.

Colonial Geological Surveys of Africa

SIR EDMUND TEALE's important address on "The Contribution of Colonial Geological Survey to the Development of the Mineral and other Resources of East and West Africa", delivered before the Royal Society of Arts, is published in the Society's *Journal* of April 13, 1945, pp. 245–56. The success of the early mineral surveys, of which the first was started n Nigeria in 1903, made it clear that larger staffs and fuller facilities for the wide extension of geological work on more systematic lines would be amply ustified. The first permanent Geological Survey was started on the Gold Coast in 1910, to be followed in 1918 by one in Nigeria, and later by others in Uganda, Tanganyika, Nyasaland, Sierra Leone and Kenya. Their economic activities are summarized as (*a*) *exploratory*: dealing essentially with investigations which yield results in the actual discovery of new deposits of minerals, or in mapping the geological features which assist prospectors or mining engineers to locate and open up mineral occurrences; and (*b*) *advisory*: including numerous forms of assistance regarding engineering, industrial, commercial, agricultural and welfare interests (for example, water supply, soil conservation and site locations). Much of this assistance, though it has far-reaching influence on colonial development, does not usually lend itself to statistical valuation.

On the exploratory side, however, actual mineral discoveries by Survey geologists have yielded direct revenue in royalties alone which have repaid many times over the total cost of all the Colonial Geological Surveys. The cumulative values of some of the more important Survey discoveries are as follows (up to 1939 or 1940):

Gold Coast	Diamonds	£7,618,186
	Manganese ore	10,062,594
Sierra Leone	Iron ore	2,640,966
	Diamonds	4,700,272
Nigeria	Coal	1,860,000

Certain other minerals, such as mica, tin and tungsten ores, and above all bauxite (of which the estimated reserves are 250 million tons in the Gold Coast and 60 million tons in Nyasaland), have afforded important supplies to the strategic mineral requirements of the War.

High Polymer Bulletin

ANYONE familiar with present developments on the academic side of micro-molecular chemistry and physics cannot fail to be impressed by the contributions made to the subject by Prof. H. Mark, now of the Polytechnic Institute, Brooklyn, New York. In this Institute there has been established a Bureau of High-Polymer Research, the business of which is to carry out research on all problems of high-polymer chemistry and to organize and to conduct courses of instruction and also discussions on various aspects of the subject. In order to let the scientific public know more about the activities of the Bureau than would be gleaned by reading papers in the scientific journals, a *Polymer Bulletin*, issued bi-monthly, has made its appearance under the editorship of Paul M. Doty. The first number gives a brief description of some of the equipment of the laboratory and of the researches now in progress, but not yet published in the usual journals. While this preview of what is to come from the laboratory is of great interest to high-polymer chemists, it is somewhat unusual, and incidentally an interesting experiment, to find an academic laboratory publishing its own 'science news'. Thus yet another publication is added to the list which a busy investigator must scan to make sure that his own work is not likely to be out of date before it is published. In a quickly advancing subject like high polymers, at the present stage the desire to found new journals inevitably arises; the measure of success depends upon what support is given to the venture in its initial stages.

The World To-day

WITH its last issue, for June 23, the *Bulletin of International News* has been replaced by a monthly review, *The World To-day*, and a *Chronology of International Events and Documents* appearing twice monthly. Each issue of the former will contain "Notes of the Month" and five or six articles. The first issue for July includes five, dealing with the municipal elections in France, the Allied zones of occupation in Germany, Germany and European reconstruction, international air transport and Guernsey under German occupation. It is hoped that by articles giving factual background to current international problems and first-hand accounts of conditions in foreign countries, *The World To-day* will help to meet the demand of the general reader for such factual information; while the Supplement will be for the specialist who requires the reference material in connexion with his work as a student of international affairs, lecturer or writer, business man or diplomat. The new arrangement will also permit the most economical use of the available paper.

Energy Regulators

THE energy regulator made available by Sunvic Controls, Ltd., operates by periodically switching the power on and off, the ratio on-time/total time determining the average power input. The regulator is generally cheaper and far less bulky than a variable resistance. The control is effected without the energy loss in a resistance, it is variable continuously from no load to full load, and is substantially independent of mains voltage fluctuations up to about 20 per cent. Two forms are available, one for industrial purposes having a minimum time-cycle of about 30 sec., and another for laboratory use with a cycle of about 10 sec. The regulator consists essentially of a bimetal strip carrying a heater winding, connected in parallel with the load to be controlled. A snap action switch is in series with the load and is normally closed, so that current flows through the heater winding and through the load. The bimetal warms up and, in bending, opens the switch, interrupting the current both to the heater winding and the load. The bimetal then cools down and the cycle is repeated. The ratio of the time during which the contacts are made to the total time of the cycle determines the average input.

Some applications of the regulator are as follows: (1) in apparatus where it is inconvenient or impossible to fit a thermostat—for example, hot plates, injection moulding nozzles, moulding platens, etc.; (2) for small, high-temperature ovens and furnaces where the cost of temperature control would be excessive; (3) for any heating process where the temperature is a function of power input only; (4) to control the rate of change of temperature in a furnace in order to reduce the temperature differential permitted by conventional temperature controllers; (5) for controlling the input to a furnace so as to obtain rapid heating-up without undue over-run at the operating temperature; (6) to control the average output of a motor driving, for example, a conveyor or pump where there is no objection to the motor being periodically started and stopped, such as a pump filling a tank or a motor driving an automatic stoker or a belt travelling through a furnace. The regulator can also be employed to obtain an adjustable time delay of 10–120 sec. and as a flasher with adjustable on/off ratio.

Future of Electricity Supply in Matabeleland

A PAPER on this subject is contributed by Mr. A. R. Sibson to the February 1945 issue of the *Journal of the Institution of Electrical Engineers* (92, Pt. 2, No. 25). Southern Rhodesia is now coming to life industrially, and the problems of electricity supply require careful consideration if the Colony is to progress on sound economic lines. In this paper, the existing economic and geographical conditions are first outlined, together with the sources of raw materials, power and water. The probable development of basic industries in Matabeleland is discussed and other possible avenues of electricity consumption are detailed, including railway traction and the natural growth of existing load centres. The author then investigates three different methods of supplying the power demand of the future, two of which involve the transmission of large blocks of power over distances in excess of two hundred miles. The peculiar problems inherent in long-distance transmission in Rhodesia are dealt with, and the economics of overhead lines operating at 250 kV. are examined. The author reaches the final conclusion that the use of hydro-electric power, up to a total of 100,000 kW., from the Victoria Falls should be seriously considered as part of a comprehensive scheme for future supplies.

Insecticides

SOME useful information about the phytopathological uses of the new insecticide D.D.T. (dichlorodiphenyl trichlorethane) has been given by H. Martin and R. L. Wain (*J. Roy. Hort. Soc.*, 69, Pt. 12, Dec. 1944). This substance, at insecticidal strength, is harmless to man and farm animals, but acts both as a contact and stomach poison to insects. D.D.T. could probably replace lead arsenate in the combined spray with lime sulphur, without any objectionable sludge of lead sulphide. Perhaps its most outstanding possibility, however, is its use as a persistent contact insecticide. It is unaffected by light and moisture, in contrast to the pyrethrins and rotenone, and offers the horticultural possibility of applying a contact insecticide at any convenient period—not, as hitherto, when the insects are actually exposed upon the plant. This should provide a useful method of control for such pests as apple blossom weevil and the leaf miners, which are usually protected from any direct spray, but move about the plant for certain limited periods. D.D.T. does not seem to have any egg-destroying properties, and is somewhat slow in action, but these defects are small in comparison with the positive benefits. A short anonymous account following the above reference directs attention to a new thiocyanate winter wash. The toxic agent β-butoxy-β′-thiocyanodiethyl ether, and this is i corporated with petroleum oil. Thiocyanate wash are non-poisonous to human beings, domestic anima and poultry, are more convenient in use than d nitro-*ortho*-cresol (D.N.C.) and give a good contr of woolly aphis, which has hitherto eluded a attempts to control it by spraying.

Palæontographical Society's Centenary, 1947

THE Council of the Palæontographical Society h accepted a recommendation from its Centenary Con mittee urging the publication of a directory of Britis fossiliferous localities. The object of the scheme to produce a small handbook from which any perso interested in fossils can ascertain where particul formations and assemblages of fossils can be co veniently studied, and where in any district there a reasonable chance of collecting typical fossil. Institutions and persons known to have an intere in geology will be circularized and their co-operatio sought in supplying data about useful localities i their respective districts. Offers of help from anyon with precise and recent knowledge of fossiliferou localities will be cordially welcomed. Further detail may be obtained from Mr. R. V. Melville, Palæontographical Society, c/o Geological Survey and Museum Exhibition Road, London, S.W.7.

Display and Bower Building in Bower Birds

MR. E. NUBLING, Normanhurst, N.S.W., ha written with reference to the paragraphs under thi heading in *Nature* of January 27, 1945, p. 105. Thes notes were intended as an acknowledgment and condensed version of a very long communication submitted by Mr. Nubling for which space could not b found in *Nature*. We regret that in preparin this abstract a mistake was made: the remark o the whole proceeding of courtship and nidificatio occurring during decreasing light refers to the lyre bird, not to the satin bower-bird as stated there.

Parliamentary Representatives of the Universities

THE following have been elected members of Parliament, to represent the Universities of Great Britain and Northern Ireland: *Oxford:* Sir Arthur Salter and Mr. A. P. Herbert; *Cambridge:* Mr. K. Pickthorn and Mr. H. Wilson Harris; *London:* Sir E. Graham-Little; *Wales:* Prof. W. J. Gruffydd; *Queen's, Belfast:* Prof. D. L. Savory; *Combined English Universities:* Miss Eleanor Rathbone and Mr. Kenneth Lindsay; *Scottish Universities:* Sir John Anderson, Sir John Orr and Sir John Graham Kerr.

Announcements

THE Lord President of the Council has appointed Dr. W. F. P. McLintock to be director of the Geological Survey of Great Britain and Museum of Practical Geology; Dr. McLintock has been deputy director since 1937.

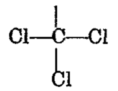
THE Ministry of Supply has agreed to the release of Dr. H. J. Gough, chief scientific officer to the Ministry. The University of Cambridge has consented to continue the loan to the Ministry of Prof. J. E. Lennard-Jones, who has been appointed chief scientific officer in succession to Dr. Gough. Prof. Lennard-Jones has been chief superintendent of the Armaments Research Department, Ministry of Supply, since 1942.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

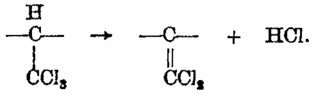
Insecticidal Action of D.D.T.

THE remarkable insecticidal powers of the compound D.D.T. (alpha alpha *bis*-(4-chlorphenyl)-beta beta beta trichlorethane) have attracted some attention for their theoretical interest as well as for their practical utilization. Two quite independent hypotheses concerning its outstanding toxicity have been published so far. They are alike in ascribing it to a combination of a toxic component of the molecule with a grouping conferring lipoid solubility; but here they part company. Dr. Läuger[1] and his colleagues believe that the toxic component is the linked *p*-chlorbenzene rings, on the grounds that they have found several compounds of this type toxic to insects when ingested. They infer that the group



$$\begin{array}{c} | \\ \mathrm{Cl-C-Cl} \\ | \\ \mathrm{Cl} \end{array}$$

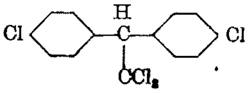
(cf. chloroform) imparts lipoid solubility. Dr. Hubert Martin[2], on the contrary, suggests that it is the chlorbenzene rings which confer lipoid solubility and that the remainder of the molecule is responsible for toxicity, by splitting off hydrochloric acid at the vital centres, thus:



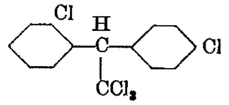
$$\begin{array}{ccccc} \mathrm{H} & & & & \\ -\mathrm{C}- & \rightarrow & -\mathrm{C}- & + & \mathrm{HCl.} \\ | & & \| & & \\ \mathrm{CCl_3} & & \mathrm{CCl_2} & & \end{array}$$

In the past year, an investigation of the toxicity of D.D.T. and a number of analogous compounds has been made in this Laboratory. The results have been considered in relation to the above theories but cannot be simply explained by either of them. The compounds most carefully examined were the following:

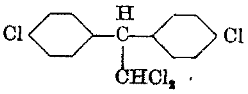
I. D.D.T. (*para para*)



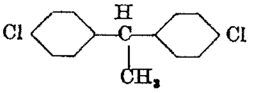
II. *iso*-D.D.T. (*ortho para*)



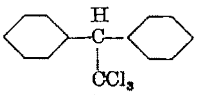
III. Dichlor diphenyl dichlorethane



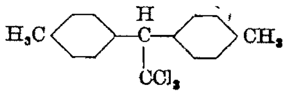
IV. Dichlor diphenyl ethane



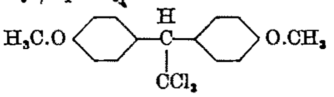
V. Diphenyl trichlorethane



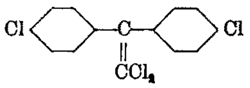
VI. Dimethyl diphenyl trichlorethane



VII. Dimethoxy diphenyl trichlorethane



VIII. Dichlor diphenyl dichlorethylene



Toxicity to Insects. Figures giving the relative toxicity of the samples were obtained for the body louse (*Pediculus humanus*) and the bed bug (*Cimex lectularius*). The samples were dissolved in refined white oil and sprayed directly on to the insects in the tower designed by Potter[3]. Concentration-mortality relations were determined by keeping the deposit constant (at 0·36 mgm. per sq. cm.) and varying concentrations. The results were plotted as log. concentration-probit regression lines, and median lethal concentrations taken from them are given in the accompanying table.

It will be observed that the relative toxicity of the various analogues is fairly similar for the two test insects. This fact, together with the evident similarity in the symptoms produced by the more toxic samples (continuous unco-ordinated activity), suggests that their mode of action is similar. The comparatively high toxicity of dimethoxy diphenyl trichlorethane (VII), especially to *Cimex*, is noteworthy. Dr. Läuger makes no attempt to explain this.

Ease of hydrolysis. The various samples were hydrolysed as 0·008 molar solutions in methyl alcohol, using $N/20$ caustic potash, at 18–20° C. The relative speeds of hydrolysis are indicated in the table by the percentages of molecules from which HCl has been split off after 240 minutes.

It is interesting to find that D.D.T. (I) is most rapidly hydrolysed under these conditions. But the dimethoxy compound (VII) remains an exception; its low speed of hydrolysis is not commensurate with its high toxicity.

Lipoid solubility. Both the theories which have been mentioned make reference to lipoid solubility, but there seems to be no actual evidence of the lipoid solubility of the complete compounds.

In order to form an impression of the lipoid solubility of the various analogues, some approximate measurements were made of their solubility in olive oil and white oil (rather similar to liquid paraffin). The results are shown in the table in comparison with the median lethal concentrations to lice and bugs.

From this table there is no evidence that the most toxic analogues are most compatible with lipoids: indeed there is a suggestion of an inverse relationship. A partial explanation of this situation was sought on the lines suggested by Ferguson[4] for various narcotic poisons. As an approximation to Ferguson's 'chemical potentials', the relative degree of saturation of the substances in the carrier liquid and hence in the phases in contact with it (cuticle waxes and lipoids) may be considered. Since the more toxic compounds are least soluble, *some* of the differences in toxicity should disappear if the insects are exposed to dry films or saturated solutions. Experiments with lice, however, gave no indication of this. The insects were confined for various periods on filter papers impregnated with saturated solutions of the compounds in white oil. The times necessary for

Sample	Toxicity : (M.L Conc.) Lice	Bugs	Hydrolysis : (% hydrolysed after 240 min.)	Solubility : (w/v% at 18° C.) Olive oil	White oil
I D D T. (*para para*)	0·3	0·53	100	10	2–3
VII Dimethoxy diphenyl trichlorethane	0 9	0 55	10	8–10	1–2
III Dichlor diphenyl dichlorethane	0 9	1 2	33	10	1–2
VI Dimethyl diphenyl trichlorethane	1 7	3·6	8	18–20	6–8
II *iso*-D.D.T. (*ortho para*)	5 5	>20	13	25	10–14
V Diphenyl trichlorethane	7·5	,,	10	25–30	10–12
IV Dichlor diphenyl ethane	8·5	,,	—	30	25
VIII Dichlor diphenyl dichlorethylene	>20	,,	—	14–18	8–10

50 per cent of the lice to pick up a lethal dose of the different substances were as widely dispersed as the median lethal concentrations, and the compounds showed the same order of toxicity.

The general conclusion to be drawn from the data presented here seems to be that, at present, there is insufficient data to formulate a theory of the action of D.D.T. Some attempts to support current hypotheses with quantitative data have met with no success. Of particular interest is the low toxicity of the *ortho-para* D.D.T. and the fairly high toxicity of the dimethoxy compound. It seems possible that the shape and size of the molecule are important.

I am indebted to Prof. P. A. Buxton for reading and criticizing this account and to Dr. J. H. Birkinshaw for suggesting the method of hydrolysis. Most of the samples were prepared at the Chemical Defence Experimental Station of the Ministry of Supply, but Nos. V and VI were made by Dr. J. G. Mitchell of the D.S.I.R. Chemical Research Laboratory.

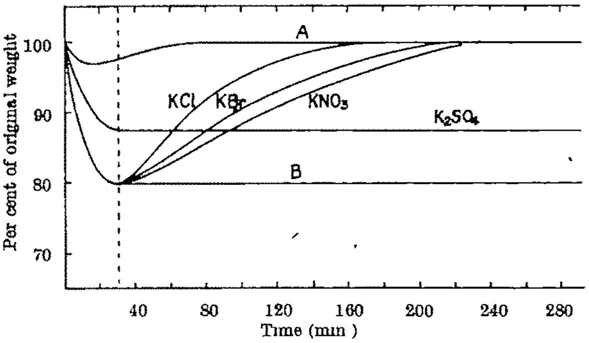
Cation and Anion Permeability Constants for the Muscle Fibre Membrane

THE following simple experiments allow of first approximate determinations of permeability constants of salts of potassium, rubidium and cæsium across the muscle membrane of the frog's sartorius. (As will be shown later, ammonium salts are unexpected in their behaviour.)

When weighed sartorius muscles of frogs are immersed at room temperature in Ringer fluid containing 110 m.eq. sodium chloride per litre plus 30 m.eq. potassium chloride (to prevent K loss) and a small addition of phosphate for buffering (about $M/500$), pH = 7·0, curve *A* is obtained for the mean muscle weight, relative to the fresh weight. After a slight fall and return (due to potassium chloride it remains steady over some hours. Throughou the immersions the muscles were stirred by bubbling with oxygen, and they are removed for weighing from time to time. If such Ringer fluid contained 21 m.eq. sodium chloride instead of 110 m.eq., curve *B* is obtained, parallel with *A* after 20–30 minutes.

When, after reaching a steady weight along the *B* curve, the muscles are removed into a simila Ringer fluid in which 100 m.eq. potassium chloride have been substituted for 100 m.eq. sodium chloride, there is a return to the normal level as shown in the graph. If the chlorine ions are replaced throughout by bromide or nitrate, the corresponding curves shown in the graph are obtained. The graph likewise shows the effect of the sulphate ion substitution (in equivalent concentration throughout).



Such experiments show very clearly (what has otherwise been fully demonstrated for potassium and chlorine ions) that the muscle membrane is permeable to potassium, chlorine, bromine and nitrate ions, also to rubidium and cæsium ions, but not to sodium and sulphate ions. Assuming that the form of the potassium chloride curve in the graph is determined solely by the entrance of potassium chloride, the entrance of water being much faster, we can write:

$$dQ/dt = D \times \frac{(C_0 - C_1)}{l_m} \times \text{surface}, \quad . \quad . \quad (1)$$

or, the rate of penetration is proportional to the gradient of concentration across the membrane multiplied by the surface and a membrane diffusion constant *D*.

Integrating this equation, it may be noted that potassium chloride outside will diffuse into the fibres, so that the concentration then added is approximately equal to the external value[1]. Hence it follows that

$$2{\cdot}3 \log C_0/(C_0 - C_1) = \frac{D}{l_m} \times t \times \frac{\text{surface}}{V}, \quad . \quad (2)$$

where C_0 is the external concentration, and C_1 the concentration of the added potassium chloride. Putting in the *t* value as that when the process is half advanced, the equation may be written

$$P = D/l_m = 0{\cdot}276\, r/t_{0\cdot5} \quad . \quad . \quad . \quad (3)$$

This value of *P*, or permeability constant (as used by Jacobs and others[3]), gives the diffusion rate per unit surface per unit concentration difference across the membrane (dimensions = L/T). When the unit of length is taken as μ and the mean value of *r* for the sartorius muscle fibre as 20 μ, then

$$P = 5{\cdot}5/t_{0\cdot5} \quad . \quad . \quad . \quad . \quad (4)$$

Inserting the values of $t_{0\cdot5}$ in minutes for potassium chloride, etc., we get for the values of *P* at 15° C.:

$KCl = 0{\cdot}12$ $RbCl = 0{\cdot}04$
$KBr = 0{\cdot}08$ $CsCl = 0{\cdot}01$
$KNO_3 = 0{\cdot}06$

hen the unit of concentration difference across the embrane is referred to a volume of one litre, these alues are multiplied by 10^{-15}, and when the second used as the unit of time instead of the minute, ey are multiplied by $10^{-15}/60$.

Besides the usual approximations involved in the etermination of permeability constants, which involve but little error, the following arises. It is sumed that no appreciable error is introduced by noring the time to reach equality of concentration the muscle interspaces and the external solution. nce the half-value period for the first part of the urve *B* is only about five minutes, it is clear that no rious error arises from this source, the value for otassium chloride as given being at most depressed y 12 per cent, and for the other salts in much lesser mounts.

If we are to attach a meaning to the permeability onstants of the separate cation and anion species in ese experiments, then it will appear that the rates or potassium and chlorine ions must each be either qual to or greater than the potassium chloride value, nd also that the figures for the single ion species, romide, nitrate, cæsium and rubidium, are near he values given for the corresponding salts.

Such figures for the permeability constants are t present being further refined upon. The experiments include studies of single fibres from the semi-tendinosus muscle of the frog.

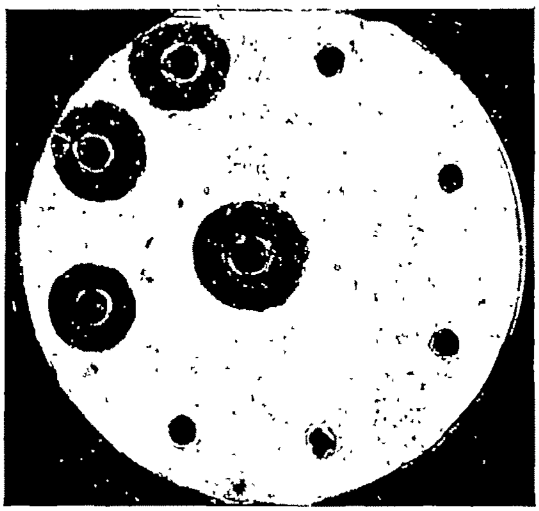
Anti-bacterial Action of 'Polyporin' against Typhoid, Cholera, Dysentery and *B. coli*

SINCE my preliminary note on 'polyporin'[1], further trials of polyporin (filtrate of a *Polyporus* sp. in Czapek-Dox medium-pH 7) have been carried out *in vitro* in plate-cultures (agar-cup method) of typhoid, cholera, dysentery and *B. coli*, 14–25 mm. clear lytic zones have been obtained (see accompanying illustration). A sodium salt of polyporin has been prepared by following with modifications the method of Berger[2]; it is found to have greater potency than the crude filtrate. In broth-cultures of typhoid and *Staphylococcus aureus* the sodium salt produces lytic action in the course of about twenty hours.

Sporophore extracts from dried fruit-body of the *Polyporus* in distilled and saline water produce clear lytic zones in plate-cultures of typhoid, cholera and *Staphylococcus aureus* (Oxford strain); thus they have distinct bacteriolytic action.

The animal experiments with polyporin have shown it to be completely non-toxic. Polyporin is non-hæmolytic; in intramuscular injections it produces no pyrogenic effect in men; it has been found that polyporin retains its potency at room temperature (22°–32° C.) for about a month if maintained in a sterile condition.



THE TYPHOID PLATE, AGAR-CUP METHOD. THE SIZE OF THE CIRCULAR ZONES BEARS RELATIONSHIP TO THE AMOUNT OF POLYPORIN IN THE FOUR CUPS.

In vivo experiments on typhoid and cholera patients in our college hospital are just going on; the results of these with short case-notes will be communicated in due course.

I wish to thank the Indian Health Institute and Laboratory, Ltd., of Beliaghata, Calcutta, for financing this research.

Microbiological Assay of Riboflavin

MR. E. C. WOOD's plea[1] for a more critical examination of the data of microbiological assays is more than timely. Such an examination not only permits a more accurate interpretation of the results; it can also give an indication of the directions in which the technique most needs improvement.

Because of the presence, in certain types of sample, of substances stimulatory to *L. helveticus*, invalid assays of the type quoted by Mr. Wood are not uncommon. The stimulation is diminished by ether-extraction of the sample[2] and by precipitation of the acid extract at pH 4·5[3], but in our experience it is frequently not entirely eliminated. Although $(a - A)$ may not be statistically significant in a *single experiment*, there is cause for concern in the fact that it is usually positive.

It is now well known that there are many substances that stimulate *L. helveticus* in the presence of sub-optimal concentrations of riboflavin, and it is obviously impracticable—even if it were desirable—to include them all in the basal medium. It is suggested, however, that a medium which gives enhanced responses with sub-optimal doses of riboflavin might be expected to yield more valid assays.

We have confirmed the superiority in this respect of the modified medium proposed by Greene and Black[4]. Higher responses have also been obtained in these Laboratories by increasing the concentration of the factors provided by yeast. Using these 'enriched' media, we have found that there is no longer a direct linear relation between dose and response, but that the curve conforms closely to the normal semi-logarithmic form. Repeatedly we have observed a linear relation between response and log dose over the dosage range 0·04–0·125 γ, and the statistical analysis of the data then follows familiar lines.

Many of the discrepancies between the figures published by different workers for the riboflavin content of the same or similar cereal samples are incompatible with the precision usually claimed for microbiological assays, namely, ± 10 per cent. Andrews[5], for example, reported wide variations between the results of individual collaborators, though a decided improvement was evident in a later survey[6]. Barton-Wright and Booth[7] found higher values for cereals than did Andrews *et al.*[8], and suggested that the latters' extracts were too concentrated.

In our view, pre-treatment of the extracts by some such method as that of Strong and Carpenter is essential for the assay of cereals with the media at present in use. We have observed also that extracts which give positive values for $(a - A)$—and, in consequence, invalid assays—yield considerably lower results on the 'enriched' media referred to above. It is suggested that the lower, rather than the higher, results are likely to be closer estimates of the riboflavin content.

The real solution of these difficulties clearly lies in improving the medium, for attempts to remove stimulatory factors from extracts are, in themselves, admissions of its incompleteness.

Records of *Culex* (*Barraudius*) *modestus* Ficalbi (Diptera, Culicidæ) obtained in the South of England

IN the years 1932 and 1940 respectively, two species of mosquitoes which are widely distributed in the Mediterranean region, namely, *Anopheles algeriensis* and *Theobaldia longiareolata*, were recorded for the first time in Britain: the former from a coastal area in Norfolk[1], and the latter from Portsmouth (Hants)[2]. When recording the first-mentioned immigrants, the late F. W. Edwards suggested that they might have been introduced into Britain by aeroplane, and it seems highly probable that the later invasion admits of a similar explanation; although the alternative that the intruders were sea-borne is admittedly (at any rate where the seaport area of Portsmouth is concerned) a possibility. As, however, no descendants of either of these invaders are known to have survived the ensuing winter, the following British records of yet another Mediterranean species may be found of interest. All the specimens concerned in the present case were collected and identified, by my assistant, J. Staley, in the ordinary course of the mosquit control operations which are carried out under h supervision throughout a coastal area of Hampshi having an area of about forty square miles.

On July 27, 1944, while inspecting coastal ditche on the mainland north of Hayling Island, Mr. Stale caught a female mosquito (after allowing it to bit him) which resembled no known British species. Thi female took a further blood meal, in the laboratory two days later, but died on August 1. On July 29 however, a similar female had been captured in house at Hayling Island, situated about three mile south of the point where the first specimen had bee taken. I will denote the points of capture of th first and second specimen by *A* and *B* respectively The second female refused a blood meal and die shortly afterwards. Reference to literature indicate that the females were of the species *Culex* (*Barraudius* *modestus* Ficalbi.

During the past three years, our control work ha included the monthly inspection of N.F.S. stati water tanks in the city of Portsmouth; and o August 24, 1944, when examining in the laborator some mosquito larvæ collected from one of thes tanks, Mr. Staley found (in company with larvæ o *Anopheles atroparvus* and *Culex pipiens*) three larva of a non-British species which corresponded in every respect with the illustrations accompanying Callot' description of *C. modestus*[3]. On the following day, before the infested water had been oiled by the N.F.S. authorities, three more similar larvæ were collected. From the six larvæ thus obtained, one male and five females were reared. Comparison of the hypopygium of the male with the illustrations given respectively by Martini[4], Barraud[5] and Callot[3] showed that of the last-mentioned writer to be the only entirely correct one.

The tank in which the larvæ were found is situated within two miles of an airport and about five miles to the south-west, and about three and a half miles to the west, of the points *A* and *B* respectively. The fact that the prevailing wind is south-west suggests that the two females captured may have originated from the tank; it is to be noted, however, that the points *A* and *B* are respectively only about two and three miles distant from an aerodrome located eastwards of them.

I reported the above facts to the local authorities concerned, but directed no other attention to the *modestus* immigrants, as I considered it extremely unlikely that any of their progeny would live through an English winter. This assumption, however, has now proved to be incorrect. On May 15 last, in a garden at Hayling Island about half a mile from the point *B*, Mr. Staley was attacked by, and captured, another *C. modestus* female: and on June 15, when examining in the laboratory mosquito larvæ collected in the Borough of Gosport district (into which our control work has recently been extended), he found four more larvæ of the species in question. These larvæ had been collected (in company with larvæ of the salt marsh species, *Aedes detritus*) in a small pool of brackish water situated within a few yards of a river and nearly five miles due west of the tank in which the '1944' larvæ had been found. As this pool had been abolished (by 'filling in') before the collected larvæ had been examined in the laboratory, no attempts to obtain additional specimens could be made. It is to be noted that the Gosport *modestus* larvæ were found in brackish water, whereas the Portsmouth ones of last year were found in a tank containing non-salt water: a fact which accords with Martini's statement that this species breeds both in fresh and partly salt water[4].

The four larvæ were placed in an incubator having an above-water capacity of about 40 cubic inches, and three males and a female eventually developed. One of the males died soon after emergence, and microscopic examination of its genitalia has confirmed he accuracy of Callot's illustrations. The female was given a blood meal on June 30, and laid an egg raft (the eggs of which duly hatched) on July 5. Callot's statement that *C. modestus* is eurygamous is therefore incorrect.

C. modestus is common in many parts of the Mediterranean region, in Asia Minor and in one part of India (Kashmir). Up to now, its most northerly record is from Richelieu, France (about two hundred miles south-west of Paris), where, according to Callot[3], "it attacks men and animals mercilessly". Ficalbi[6] has stated that this species "frequents woods and thickets but also enters houses"; that "it bites during the day, the twilight and the night"; and that "its bite is very painful".

Whether *C. modestus* is further extending its range in Britain remains to be seen. It would obviously be an undesirable addition to the list of British species.

Granules of the Human Polymorphonuclear Leucocyte

THE oxidase granules of the human polymorphonuclear leucocyte are taken to be protein in nature. Characteristic of the later myeloid cells, these granules are examined in the leukæmic blood disorders in an attempt to define the origin of primitive cells, although the technique for their demonstration is not too easy. This note describes a simple method for the staining of the granules and suggests that they are composed of, or contain, lipines.

Air-dried blood films are fixed for one minute in acetone and air-dried again. Pass the slide through 70 per cent alcohol and leave for ten minutes in a saturated solution of Sudan Black in 70 per cent alcohol. Rinse well in three to six changes of 50 per cent alcohol. Dry in air. Stain with Leishman's or any other of the routine blood stains.

The polymorphonuclear leucocytes show their cytoplasm to be packed with discrete fine granules. These cells are the only ones in the blood smear with the granules, the lymphocyte and monocyte lacking them.

It is noteworthy that the stain used for the demonstration of the granules—Sudan Black—was introduced by Lison[1] as being soluble in all, or nearly all, classes of fats and in fats only. About two per cent of the polymorphonuclear leucocytes contain fat with Sudan IV and this is taken as an indication of aging. The fact that the granules stain with Sudan Black and not with Sudan IV suggests that they are lipine in nature, or contain lipine, and their insolubility in acetone suggests that they are lecithin although by no means proving the point. The fatty nature of the granules seems to be proved finally by their complete solution in ether-alcohol.

Preliminary studies indicate that the Sudan Black granules are present in the cells of the late myeloblast series, as seen in narrow punctures, and that none of the cells obtained in lymph node punctures contain such structures. The granules persist during purulent processes and appear to pass out into the pus. No gross change is noticeable in these granules as a result of fasting or feeding, or in the usual infections encountered in an army general hospital. Studies are being undertaken to investigate the utility of the method in the leukæmias and to demonstrate the Sudan Black material in the leukocyte in various disorders of fat metabolism.

Origin of Haploid-Diploid Twin Embryos in Angiosperms

IN an interesting article entitled "The present status of Plant Embryology" Dr. Donald A. Johansen[1] makes the following observation (p. 101) regarding the origin of polyembryony: "To cite another instance, if one of the twin seedlings is haploid and the other diploid, it can ordinarily be taken for granted that the diploid seedling arose from a fertilized egg, while the haploid seedling developed either from an unfertilized synergid or from the nucellus or inner integument".

Regarding the first part of the statement, it is necessary to point out that the tissues of the nucellus and inner integument have the sporophytic number of chromosomes and hence any embryo arising from these must be diploid and *not* haploid. Adventive embryos of this kind are of a metromorphic type resembling the maternal parent in chromosome number and other characters.

In respect of twin seedlings, of which one is haploid and the other diploid, it is not easy to be sure if the latter arose from a fertilized egg and the former from a reduced but unfertilized synergid. Kihara (1936; quoted by Cooper[2]), who reported a case of haploid-diploid twins in *Triticum durum*, believes the reverse to be the case, namely, that the haploid member arose from an unfertilized egg and the diploid member from a fertilized synergid. Yamamoto[3] postulated a similar origin for the twins found by him in *Triticum vulgare*. There are also cases on record of antipodal cells giving rise to embryos, which may be diploid or haploid depending on whether any nuclear fusions took place or not prior to the cell undergoing divisions to give rise to the embryo. In *Poa arctica*[4], the origin of the twin embryos, one haploid and the other diploid, has been traced to two different embryo sacs, one originating from a megaspore and therefore having the reduced number of chromosomes and the other originating from a nucellar cell (aposporous) and therefore diploid. The eggs of both the embryo sacs develop parthenogenetically, giving rise to one haploid and one diploid embryo.

Briefly, then, while in any case of twin seedlings, one haploid and the other diploid, it is quite possible and even likely that the former has arisen from an unfertilized synergid and the latter from a zygote, the condition needs careful scrutiny before any judgment can be given. Adventive embryos, however, whether originating from the nucellus or the integument, are diploid.

Origin of Toxicity to Fungi in Wareham Heath Soil

Dr. Brian's discovery of marked antibiotic activity by species of *Penicillium* present in Wareham soil is a welcome addition to our knowledge of the factors directly responsible for the observed inhibition of microbiological activity in this soil, with the resulting pronounced biological inertia and infertility for plant growth[1].

The presence of a factor or factors of biological origin actively toxic or antagonistic to fungus growth and normal root development was suggested by me in a paper published in 1934[2]. The correctness of this hypothesis was later fully established[3]. It would have been indeed a fortunate coincidence if the discovery of penicillin and realization of the important part played in Nature by the production of bacteriostatic and fungistatic substances had come in time to direct attention at that stage of the work to the species of *Penicillium* observed in samples of Wareham soil, more especially in those selected as likely to exhibit the highest degree of toxicity.

Incidentally, our observations suggested that the distribution and abundance of the soil *Penicillium* spp. present is sporadic throughout the experimental area and possibly influenced by seasonal conditions. Until further data are available, it must remain an open question whether gliotoxin as such is the immediate cause of all the observed phenomena in Wareham soil, including especially limitation of growth of those mycorrhizal fungi known to be present involving either complete failure of mycorrhizal activity, or the development of mycorrhizas structurally and functionally abnormal; or whether this substance is one—perhaps the chief initiating cause—of a number of disturbances of microbiological origin leading ultimately to soil infertility. The differential susceptibility of air-borne micro-organisms present on plates tested by the agar-film method had been noted and the resistance of *Penicillium* spp. as compared with *Mucor* spp. and other air-borne infections is possibly of some significance.

Dr. Brian's observations on the mycorrhizal and other fungi sent to him are of particular interest. Of these fungi, *Boletus bovinus*, *B. elegans*, *Mycelium radicis nigrostrigosum* and *Phoma radicis callunæ* are mycorrhiza-formers. *B. bovinus* was the only known mycorrhiza-former of pine and spruce initially present throughout the area. *B. elegans* does not occur on the area but appears in adjoining woods of larch, of which it is a proved mycorrhiza-former; nor has *Mycelium radicis nigrostrigosum* ever been observe unless introduced in soil inocula, although this fung is extremely abundant as a mycorrhiza-former i woods of Scots pine adjoining the area. *Phom radicis callunæ* is the mycorrhiza-former of *Callun vulgaris*, a natural dominant on Wareham heath.

The differential susceptibility of these mycorrhiz fungi to gliotoxin, as recorded by Dr. Brian, is i agreement with all observations and facts relatin to growth activity in the case of those present o the experimental area, and, in the case of those n present, for example, *B. elegans* and *M. radic nigrostrigosum*, accords with expectation.

The case of *Phoma* is of special interest. Th endophyte shows relatively slight susceptibility, a might be expected from its wide distribution throughout the area in mycorrhizas of *Calluna*. That som susceptibility exists is in agreement with observations made by me at an early stage of the Wareha researches in respect of relatively slight and varying degrees of abnormality in mycorrhizal developmen and structure observed in mycorrhizas of *Callun vulgaris* on the heath-land before ploughing.

The reaction of the pseudomycorrhiza-former *Mycelium radicis atrovirens* and *Rhizoctonia* sp. is als of interest. *M. radicis atrovirens* is present throughout the area, but is relatively rare and has not been observed to attack either pines or spruces in the field. *Rhizoctonia silvestris*, the form sent to Dr. Brian, does not occur in Wareham soil. In respect of *M. radicis atrovirens*, it would be of particular interest to have a comparative test of a form imported in a Swedish soil that proved to be highly pathogenic to Norway spruce under Wareham conditions[4].

The title given to Dr. Brian's communication is unfortunate. The use of 'mycorrhiza' in the singular to describe the general phenomenon is now recognized as incorrect and has been given up by those familiar with the facts. The toxicity recorded by Dr. Brian is to 'mycorrhizal fungi' and not to 'mycorrhiza'.

Nutritive Value of Coco-nut

The communications on the nutritive value of coco-nut by Dr. Lucius Nicholls and Sir Jack Drummond[1] were read by us with interest.

In 1941, while working with the microbiological assay of vitamins, stories of seamen and aviators stranded on 'coco-nut isles' became common, and it occurred to us to measure the vitamin content of the 'coco-nut milk' popularly supposed to be the dietary mainstay under such conditions. The values listed are those obtained for the centre fluid of an apparently normal specimen obtained at a local grocery store.

Nicotinic acid	0 04	micrograms/c c.
Pantothenic acid	0 52	,,
Biotin	0 02	,,
Riboflavin	< 0 01	,,
'Folic acid'	0 003	,,

The concentration of two other vitamins for which microbiological assays were not available, thiamin and pyridoxine, were so low as to be negative toward olour tests, even though the material was first conentrated to some extent by adsorption and elution.

It is evident that the juice was not of high nutritive quality. The minimum daily requirement of riboflavin, for example, according to the Food and Nutrition Board of the U.S. National Research Council, for a 'very active' individual of 70 kilos is 3·3 mgm. per day. To meet this requirement, the daily consumption of coco-nut juice would have to be at least 330 litres.

Spectral Analysis of Solid Substances

A METHOD has been developed whereby it is possible to deduce from a single spectral photograph not only the qualitative analysis of a totally unknown mineral powder, but also its *approximate* quantitative composition.

For this purpose mixtures have been made of all spectrographically detectable elements at our disposal; the concentrations were 10, 3, 1, 0·3, 0·1 down to 0·0001 per cent. Pure, washed quartz-sand was used as a basis for the various dilutions.

In order to reduce the amount of work and time required for the preparation of the standard spectrograms, the elements which had to be considered were divided into groups of ten, the sensitive lines of which do not coincide. Quantities of the pure chemical compounds, equivalent to 100 mgm. of the oxides, of all elements of the same group were thoroughly mixed in an agate mortar under alcohol. One tenth of this mixture was added to 900 mgm. of the pure quartz powder, thus obtaining a mixture containing 1 per cent of each of the oxides concerned.

The lower concentration steps have been obtained by diluting this 1 per cent mixture with a calculated amount of pure silica. The higher concentration steps have been prepared as follows: (*a*) for the 10 per cent mixture: 100 mgm. of the oxide of each element were mixed with 900 mgm. of pure silica; (*b*) for the 3 per cent mixture: 300 mgm. of the 10 per cent mixtures of each member of a subgroup of three elements of the same group were ground with 100 mgm. of the pure quartz sand.

Before taking the spectrogram, each mixture was mixed again with half its weight of sodium carbonate.

The photographs were taken with the continuously burning electric arc between very pure, plane carbon electrodes of 5 mm. diameter. The arc burns for 60 sec. at 4 amp., and then for 30 sec. at 7 amp. We used a Hilger E.315 quartz spectrograph. A diffusely and uniformly illuminated slit is obtained by focusing the arc sharply on a screen in which is inserted a rectangular diaphragm; the illuminated opening of this screen is focused enlarged on the collimator lens of the spectrograph.

A rotating step sector (factor $r = 3{\cdot}5$) was placed before the slit of the spectrograph. The intensity of the lines chosen for analysis is compared for each concentration with the intensity of certain Si-lines from the spectrum (the concentration of silica being approximately constant). This comparison is performed visually, under a twenty-fold enlargement, with a Zeiss spectral projector. The relative intensity (rather the relative exposure) is denoted by the difference in the number of 'steps' to be applied to the two lines under comparison in order that they may show equal blackening[1].

For the lowest concentrations a spectrum is taken with illumination forming an image of the arc on the slit, without a step sector, the cathode layer effect being used. Again the intensities of the weak lines are compared with those of the Si-lines of the stepped spectrum.

Tables have been drawn up, giving the relative intensities as a function of concentration, for the most prominent lines of fifty-six different elements.

A number of synthetic mixtures have been prepared, and then analysed by means of the method described, with the aid of the data of our tables. Some results are given in the accompanying table, which includes also the results for a natural mineral (tourmaline).

It will be seen that a fair estimate of the concentration of the elements present is obtained.

I			II			III (tourmaline)		
	Calculated	Found		Calculated	Found		Chemical analysis	Spectral analysis

A Tetrabromide of β-Phellandrene

IT has been generally accepted that β-phellandrene does not form a tetrabromide, and indeed we have found no reference in the literature to the formation of such a compound by a conjugated terpene apart from a recent record of a liquid tetrabromide derived from α-terpinene[1]. During examination of the terpene fractions of the oil from *Eucalyptus cneorifolia*, we repeatedly isolated a crystalline tetrabromide which had m.p. 110–112° and was *dextro*-rotatory. After recrystallization from ethyl acetate, the melting point rose to 118–119°, the specific rotation being almost + 54°.

Microanalysis established the formula of the substance as $C_{10}H_{16}Br_4$, and the hydrocarbon recovered on treatment with magnesium and ether[2] showed the characteristic features of *l*-β-phellandrene, forming, for example, a nitrosite[3] and a nitrosochloride[4]. That the tetrabromide was derived from this hydrocarbon was supported by the formation of a crystalline derivative from a sample of *l*-β-phellandrene isolated from Canada balsam oil. This had practically identical physical properties, and on admixture with the sample from the eucalyptus oil there was no depression of melting point.

The chief feature of the tetrabromide from β-phellandrene is the change of sign of rotation, the *lævo*-rotatory hydrocarbon giving a *dextro*-rotatory tetrabromide. The investigation was further extended by formation of a crystalline tetrabromide from a sample of *d*-β-phellandrene derived from water fennel oil (*Phellandrium aquaticum* L.)[5]. This also had a melting point of 118–119° and had a specific rotation of − 53°.

A detailed account of the work will be published elsewhere.

Symbols Used to Indicate Hydrogen Ion Concentration and Similar Quantities

THE symbols pH and pK, commonly encountered in chemical literature, each consist of two letters, the second of which may, or may not, be used as a subscript, and either or both of which may be set alternatively in roman type or in italics. There appears to be no generally accepted convention governing the choice from the many resulting possible forms, and inconsistencies are often encountered even within a single published article.

According to its origin, the letter 'p' in the symbol pH is an operator describing a function of the variable denoted by the letter 'H'. Presumably in order to show the different significances of the two letters in the compound symbol, it was originally written with a subscript 'H' by Sörensen. This arrangement, besides being somewhat inconvenient, seems to give undue prominence to the operator. In the more recent and common form $p\mathrm{H}$, the difference in type sufficiently marks the different duties of the two letters, but is opposite in direction to that conventionally used in other functional symbols, such as log T or dt. From this point of view, $\mathrm{p}H$ appears a more consistent form. There is, however, much to be said in favour of dropping the distinction in type between the two letters, and of regarding the quantity denoted by pH as an important independent variable without reference to its derived origin. Although the compound symbol may have a unique meaning, this is not necessarily true for its component letters; thus, H may denote a concentration and p a negative logarithm, or—sometimes more conveniently —H a dilution and p its logarithm. It is suggested that, in agreement with the accepted convention for single-letter symbols, all compound symbols in which p is used as an operator should be set in uniformly italicized type, as pH, pK, etc., without speci advertisement of their derivations.

In chemical texts, the symbol pH (or its ty variants) is commonly used as a noun, as in t phrase "The determination of pH", though for th purpose it is sometimes expanded to 'pH value There is little to be said in favour of 'pH value which is longer, and no more descriptive, than p If the demand for brevity constrains us in the futu to replace the noun 'time' by the symbol t, the inco sistency of 't value' will quickly become obviou Much the most common plural form of the noun 'pH values' (or its type variants), a fact that prob ably reflects our uncertainty as to the correct plural of the letters of the alphabet, and our resolve t mind our grammatical P values and Q values. Th correct plurals of $p\mathrm{H}$, $\mathrm{p}H$, pH and pH are respectivel pH's, pHs, pH's and pHs. The rule is simpl If there can be any doubt whether the final 's' is plural ending or a part of the symbol proper, a apostrophe is required; but if a difference in typ between the final letter of the symbol proper an the plural 's' avoids this ambiguity, no apostroph should be used.

Unshrinkable Wool

ONE of the more recent processes for making woo unshrinkable consists in synthesizing an organi polymer on the surface of the fibres[1], thus masking the surface-scale structure which is the primary cause of shrinkage. Precisely similar results may be obtained with inorganic polymers.

For example, when flannel is immersed in a solution of silicon tetrachloride in carbon tetrachloride, a vigorous reaction takes place between the adsorbed water of the wool and the silicon tetrachloride, a siliceous deposit being formed on the surface of the fibres. In consequence, the treated fabric shrinks very much less than untreated fabric during milling, as may be seen from the following data. These were obtained by treating 2·5 gm. patterns of flannel, previously conditioned at 65 per cent relative humidity and 22·2° C., with 100 c.c. of a solution of silicon tetrachloride in carbon tetrachloride for five minutes at 25° C. After treatment, each pattern was washed in two changes of 100 c.c. of carbon tetrachloride, followed by running water overnight, and the series of patterns was then milled by hand in 5 per cent soap solution.

Concentration of silicon tetrachloride (per cent by volume)	Percentage shrinkage in area during milling
0	28 9
2	18 9
5	6·2
7	3 6
10	2·6

A high degree of unshrinkability is readily obtained, and it is clear that polymerizable inorganic compounds are likely to find important practical applications in the wool textile industry.

A New Test for 2 × 2 Tables

If an experiment yields results in the form of a × 2 table:

	P	not-P	Total
A	a	c	m
B	b	d	n
Total	r	s	N

here m and n have been fixed in advance, a test r deciding whether there is evidence of association etween the attributes A and B and the mutually xclusive and exhaustive attributes P and not-P has een given by Fisher[1]. This test, on the null hypoesis of no association, associates the results with probability $m!n!r!s!/N!a!b!c!d!$.

It has been usual in the past to apply this test, or me approximation to it[2,3], in cases where we can sume that the probability p_1 that A has P and the robability p_2 that B has P are both constant. The ypothesis tested then becomes $H(p) \equiv p_1 = p_2 = p$.

It is, however, possible to construct a more powerl test of the hypothesis $H(p)$ on the data given. he table above can be represented geometrically by e point (a,b) in a plane lattice diagram of points ith integer co-ordinates. Since m and n are fixed advance, all possible results will then be represented y points of the lattice lying in a rectangle bounded y the x and y axes and the lines $x = m$ and $y = n$. he hypothesis $H(p)$ assigns a 'weight'

$$W(a,b,p) = (m!n!/a!b!c!d!)p^r(1-p)^s$$

the point (a,b). To obtain a valid test of $H(p)$ on gnificance level α, we have only to choose a region R the rectangle such that

$$\underset{0 \leqslant p \leqslant 1}{\text{Max}} \sum_R W(a,b,p) \leqslant \alpha.$$

This validity condition does not determine R niquely. To obtain a reasonable test, we must reuire that R should consist of as many points as ossible, and should lie away from that diagonal of he rectangle which passes through the origin. ormulated mathematically, these latter requireents mean that the complement of R must in a ertain sense be convex, symmetrical and minimal.

For example, when $m = n = 3$, and $\alpha = 1/32$, R onsists of the two points (3,0), (0,3). The correspondng level of significance with Fisher's test is 1/10. hus the new test is more powerful than Fisher's.

The computation involved in making tables for the ew test is heavier than with Fisher's test. But once repared, the tables for the new test are on the whole nore convenient in use.

The relationship between Fisher's test and the new est is similar to that between Pitman's 'exact' test or identity of two distributions and the correspondng t-test. For large values of a, b, c and d, the differnce between the two tests becomes small. For large n,n and small a,b, there is an analogue of the new rocedure, just as there is an analogue of Fisher's[4].

This work has been carried out as part of the rogramme of the Ministry of Supply. Full details, ith tables, will be published elsewhere.

Crystal Structure of Barium Titanate

Recently Rooksby[1] and Megaw[2] have reported a tetragonal structure for barium titanate. This is of interest to us because we also have obtained X-ray powder photographs of barium titanate, from which we have established a tetragonal structure. In addition we have obtained photographs of a lattice which at first was regarded as near cubic, though in view of our subsequent findings, it appears more correct to regard it as being near tetragonal. However, the reversible temperature change of structure from tetragonal to cubic reported by Miss Megaw[2] raises the question as to whether this cubic structure might not exist at ordinary temperatures, as a result of heat treatment, or method of preparation, or presence of impurities.

The energy difference between the structures may not be large, but the change from tetragonal to cubic would appear to involve a rearrangement of the ions if the cubic structure is to be regarded as of the ideal $G5$ type, as hitherto assumed[3]. The change in structure may be connected with a very slight change in the Ti—O bond-length.

Particle Shape

The recent letters in *Nature* by Messrs. Whittaker and Tomkeieff[1] make no mention of the extensive investigations of particle shape carried out in connexion with road aggregates. A bibliography of the subject is given in my first paper[2].

In my work at the Road Research Laboratory[2,3], shape was defined in terms of the principal dimensions of the particle, which correspond roughly to its length, breadth and thickness. The ratios of length to breadth and thickness to breadth are taken as a measure of the degree of elongation and flakiness of the particle. By selecting arbitrary limits, it is possible to determine the amount of 'elongated' and 'flaky' particles and to express these in percentage by weight as indexes of shape. This assumes a more or less regular distribution of particle shapes in such materials, which has been found to be the case in practice[2,3]. This is the basis of the method adopted in British Standard 812: 1943, "Sampling and Testing of Mineral Aggregates Sands and Fillers" (Method 2).

This method, of course, only gives a partial definition of particle shape. An obvious omission is the degree of roundness of the particles, which is independent of the 'shape' as defined above. Another shape characteristic is the angularity of crushed particles. Particles classified on length and thickness can be further classified according to these characteristics. The shape characteristics of interest to any industry must be determined to suit the particular case.

RESEARCH ITEMS

Previously Spawned Salmon in Irish Rivers

ARTHUR E. J. WENT has discussed the question of the proportion of previously spawned fish in different Irish rivers (*Sci. Proc. Roy. Dublin Soc.*, **24** (N.S.), No. 1, March, 1945). The results are given of the examination of scales from fish taken from nineteen rivers; 25,029 scales were examined, of which 1,078 or 4·3 per cent were from previously spawned fish. Only 1·1 per cent of these had spawned previously on two occasions. None had spawned three or more times. It is found that where there is a large commercial fishery in the tidal waters, there is a tendency for the proportion of previous spawners to be low, but when there are one or more lakes on the river the proportion appears to be high, with few exceptions. Comparing the results with earlier investigations, it is shown that the estimated proportion of previous spawners for the country as a whole is 4·3 per cent. Kelts have little food value, but after recovery may be almost double their original weight—a good reason for protecting them.

Effect of Sulphanilamide on the Sugar Consumption of *Bact. coli*

FURTHER examination of the influence of sulphanilamide compounds on *Bact. coli* (*Prak. Acad. Athens*, **15**, 472; 1940) has been recorded by N. Klissiūnis (meeting of Feb. 10, 1944, of the Academy of Athens). Sets of flasks containing 0·4 gm. sugar and 12 c.c. of a 4 per cent peptone-sodium chloride solution were prepared, to some of which sulphanilamide 'prontalbin' was added. After sterilization at 110°, the medium was inoculated with a suspension of *B. coli* and incubated at 37° and at 41°. Four days later, the cultures were boiled, and after precipitation of the albumin by a solution of lead subacetate and subsequent neutralization of the excess lead with sodium sulphate, the flasks were filled up and the contents filtered. A portion of this filtrate was examined for sugar by Bertrand's method. It was found that more sugar had been decomposed in the flask not containing sulphanilamide. The *p*H in presence of sulphanilamide was also slightly changed, while in the controls the *p*H increases to 4·4. The bacteriological examination shows that at 41°, in presence of sulphanilamide, the *B. Coli* were killed more quickly than at 37°.

Blind Seed Disease of Rye-grass

A DETAILED account of the blind seed fungus of rye-grass crops has recently been published by Malcolm Wilson, Mary Noble and Elizabeth G. Gray (*Trans. Roy. Soc. Edin.*, **61**, Pt. 2, No. 12, 327; 1945). The fungus was originally named *Phialea mucosa* but the present authors agree that it is possibly identical with *P. temulenta*. Infected seed shows no external disfigurement, but removal of the glumes reveals caryopses, rusty brown in colour, with masses of macroconidia. No seedling emerges when the seed is sown; it apparently remains undeveloped until May of the following year, when apothecia are produced by the fungus. Ascospores from these fructifications enter between the glumes of the flowering rye-grass and attack the developing seed. The disease was serious in 1938 and 1939, but does not seem to have given a great amount of trouble since. Strains of the fungus producing mycelium only, or mycelium and macroconidia, were found, though both types bore microconidia. The paper discus possible relationships of the causal organism wi endophytic fungi of the rye-grass and related speci and its possible toxicity to farm animals is also co sidered. Several methods of control have been trie though not with much success as yet—the paras is protected against dry seed disinfectants by t glumes.

Phosphorus Deficiency of Fruit Trees

Both in Great Britain and in America phosphor deficiency of fruit trees in the field is of rare occ rence, but L. R. Bryant and R. Gardner (*Proc. Am Soc. Hort. Sci.*, **42**, 101; 1943) describe sympto exhibited by pears grown in a soil in which su flowers responded exceptionally well to phospha dressings. The leaves of the pear were smaller th normal and showed a severe marginal and apic burning early in the season. Fruit failed to devel and there was a die-back of new shoots. Pot cultu indicated that the development of these sympto could be prevented by the addition of superphospha to the soil. Sulphur (10 lb. per tree) too was benefici but potash dressings were without effect.

Use of Carbon Dioxide in Fruit Storage and Transport

A NUMBER of papers (*Proc. Amer. Soc. Hort. Sc* indicate some of the ways in which carbon dioxi may be employed to reduce losses during transpo and short-period storage of fruits. F. Gerhard E. Smith and H. English (**38**, 243; 1941) find th in an atmosphere containing carbon dioxide ripeni of apricots is retarded. The effect is almost as gre with five per cent as with twenty per cent carbo dioxide; but if the period required for ripening e ceeds ten days, mealiness, a pale colour and insip flavour and discoloration near the stone may resul but the ill-effects of the carbon dioxide are muc less noticeable at low (30° F.) than at higher (45° F temperatures. Peaches are more tolerant of carbo dioxide and do not deteriorate if the carbon dioxi concentration reaches twenty per cent. Fifteen p cent of carbon dioxide in the atmosphere will mai tain strawberries in good condition for three to fo days at 50° F., the colour being retained better a this temperature than at 32° F. (A. V. Doreen, M. H Hoffman and R. M. Smock, **38**, 231; 1941). Swee cherries may be kept for three weeks at 40° F. i air containing twenty per cent of carbon dioxide and with this concentration of carbon dioxide, brow rot and other decays of the fruit are checked. Te per cent of carbon dioxide and a temperature o 42° F. retard the ripening of plums as effectivel at a temperature of 32° F. in ordinary air (F. W Allen, W. T. Pentzer and C. O. Bratley, **44** 141; 1944). The use of carbon dioxide permit the storage of plums at a higher temperature tha would otherwise be possible, and this is importan as with some varieties breakdown occurs unless th storage temperature is above 40° F. (W. T. Pentze and F. W. Allen, **44**, 148; 1944).

Post-Jurassic Intrusions of the Aldan Region, Eastern Siberi

A VALUABLE contribution by Y. A. Bilibin to the petrogenesis of alkaline igneous rocks has been pub lished in *Petrography of U.S.S.R.*, Ser. 1, *Regiona Petrography* No. 10; *Inst. Geol. Sci., U.S.S.R. Acad Sci.*, 1941 (in Russian). The Aldan Plateau, betwee the Lena River and the Stanovoi Mountains, consist of a Pre-Cambrian complex with flat overlyin ambrian limestones and Jurassic shales. Later trusive rocks show the following sequence:

1. Concordant masses of porphyry with or without quartz, gether with melanocratic varieties.
2. Laccoliths, stocks and dykes of a wide range of alkali rocks, cluding pseudoleucite-syenite, -porphyry, -tinguaite and -leucitite, d shonkinite, foyaite, pulaskite, solvsbergite and bostonite.
3. Laccoliths, stocks and rare dykes of fine-grained calc-alkali cks, including monzonite, augite-syenite and melanocratic syenite.
4. Stocks and dykes of aegirine-granite, grano-syenite and corre-onding porphyries.

he author discusses the various hypotheses that ave been suggested to account for the origin of lkali rocks. Desilication by limestone assimilation rejected for this region on the grounds that (*a*) lkali rocks occur not only in the Cambrian lime-tones but also in the Pre-Cambrian complex, even t levels 300–400 m. below the base of the limestone; nd (*b*) contact action against the limestone is emonstrably negligible, except by the augite-yenites, where the reaction products are basic ioritic rocks. Concentration of alkalis by volatiles is ismissed, since there is no mineralogical evidence f the former presence of any unusual abundance of olatiles. It is inferred that the rocks were not pro-luced by magmatic differentiation at the levels now xposed. The author suggests the possibility that issociation of, for example, the leucite molecule takes lace at depth. By differential diffusion of the liber-ted constituents, the peripheral zone of the magma eservoir becomes enriched in K_2O; the intermediate one in K_2O and SiO_2; and the central part in Al_2O_3.

Atomic Weight of Beryllium

THE accepted international atomic weight of beryllium is 9·02. This is almost 0·1 per cent smaller than the value given by the most recent determination by the mass spectrograph—9·0126—reported by Flügge and Mattauch (*Ber.*, **76**, 1; 1943). Johannsen (*Naturwiss.*, **31**, 592; 1943) has therefore undertaken a revision of the atomic weight of beryllium by chemical methods, using the ratios $BeCl_2 : 2Ag$ and $BeCl_2 : 2AgCl$. This method was used in 1922 by Hönigschmid and Birckenbach (*Ber.*, **55**, 4) who obtained 9·018 for the atomic weight. In the present work, pure beryllium chloride was made by the action of chlorine on beryllium oxide and sugar charcoal at a red heat. The substance was then sublimed, first in an atmosphere of chlorine, then in nitrogen, and finally in a high vacuum, without the substance melting, thus avoiding any action on the containing vessel. The sublimed chloride was a snow-white, micro-crystalline mass. The substance was weighed in evacuated sealed tubes, which were then broken under water. The chlorine in the solution was determined against silver by the nephelometric method. Eleven determinations of the ratio $BeCl_2 : 2Ag$ gave values lying between 9·012 and 9·015, the mean value being 9·013 ± 0·0007. Ten determinations of the ratio $BeCl_2 : 2AgCl$ gave values lying between 9·011 and 9·015, with a mean of 9·013 ± 0·0012. The most probable value of the atomic weight of beryllium is thus 9·013, agreeing well with the mass-spectrographic value.

Separation of Casein

ALTHOUGH there was evidence that casein is not a pure homogeneous protein, it was not until Linderstrøm-Lang and Kodama, in 1925, published solubility studies that casein was definitely known to be a mixture. In 1939, Mellanby reported an electrophoretic study, finding three peaks, which he designated α, β and γ casein. R. C. Warner (*J. Amer. Chem. Soc.*, **66**, 1725; 1944), by an application of the Tiselius electrophoretic method, correlated with methods of chemical fractionation designed to be as mild as possible, finds a separation into two fractions, α- and β-casein, which represent the two peaks in the electrophoretic pattern of casein at *p*H 7. The fractions were not electrophoretically homogeneous under all conditions, but they were purified so that neither fraction contained any of the other. The possibility of the existence of complex formation between α- and β-casein is discussed.

Long Transmission-line Problems

IN a recently published paper (*J. Inst. Elec. Eng.*, **92**, Pt. 2, No. 25, Feb. 1945), R. H. Paul presents two rigorous methods of solving transmission-line problems which avoid the use of charts or tables of hyperbolic functions of complex angles. In the first of these, the voltage and current at any point are shown to be due to two waves, one travelling forward, the other backward, attenuating as they travel, the vectors of the two waves being calculated from receiving end conditions. From these the wave vectors at any other point are derived and the latter, when compounded, lead to the voltage and current at that point. In the second method the complex angle of the load is determined from the forward and backward wave vectors and to this is added the complex angle of the line. The voltage and current are proportional to the hyperbolic cosine and sine respectively of the total angle. The magnitudes of these can be calculated, using circular and hyperbolic functions of real angles. A semi-graphical method of finding the current and voltage at several points on the line is then developed.

Southern Comparison Stars for Eros

R. H. Stoy and A. Menzies, in "Re-Observation of the Magnitudes of the Southern Comparison Stars for Eros" (*Mon. Not. Roy. Astro. Soc.*, **104**, 298; 1944), have produced a sequel to an earlier paper in which an attempt was made to link the Cape magnitude system with the international system. The earlier paper was based on the observation of certain members of the Hyades, Præsepe and Pleiades clusters; but owing to the absence for these stars of well-determined magnitudes on the international scale, the attempt was not altogether a success. For this reason re-observations of some of the southern comparison stars of Eros have been conducted at the Royal Observatory, Cape of Good Hope, and comparisons of these with other results are interesting. Table 2 gives the magnitudes, on the Cape system, of 247 of the stars which were used as comparisons for Eros during its 1931 opposition, and of 86 brighter stars in the same region of the sky. On comparing these magnitudes with those determined at Yerkes and Mount Wilson, it is seen that the Yerkes magnitudes require a large systematic correction, depending on the declination, for both photographic and photovisual magnitudes. The lower the stars are in the sky at Yerkes, the brighter they appear, and it seems probable that something of this systematic effect has been carried over into the Mount Wilson magnitudes. Some of the causes for this effect are discussed, and in view of the large systematic errors that affect both the Mount Wilson and Yerkes magnitudes of the Eros comparison stars, neither series can be regarded as an accurate representation of the international scale as embodied in the North Polar sequence.

SWEDISH OCEANOGRAPHY DURING THE WAR

By PROF. HANS PETTERSSON
Oceanografiska Institutet, Göteborg

ON January 24, 1939, the Oceanografiska Institutet in Göteborg, given to the Royal Society of Göteborg by the Wallenberg Foundation, was inaugurated[1]. Since then it has worked in close co-operation with the Svenska Hydrografisk-Biologiska Kommissionen, which has in this way received a valuable addition to its own research facilities, Bornö Station and Havsfiskelaboratoriet, both situated at the Gullmar Fjord, and the research ship *Skagerak*. At the beginning of August 1939 the *Skagerak* was engaged on an international cruise in the Baltic. One month later the ship was commandeered by the Swedish Navy and has since then been serving as an auxiliary gun-boat.

Cut off in this manner from active work at sea, Swedish oceanographers have had to fall back on work in the laboratory and within territorial waters on board chartered vessels. Occasionally, thanks to the courtesy of the naval command and of the Hydrographic Office in Stockholm, short cruises for special purposes have been carried out with the *Skagerak* and with the survey ships *Gustaf af Klint* and *Svensksund*. Some results gained in the course of five years work are summarized here.

Current measurements in the Baltic made with O. Pettersson's recording current meter suspended from submerged carrier buoys had in 1931 led to the discovery of rotating 'inertia-currents' with a period of twelve pendulum hours. During the cruise in the summer of 1939 four ships were co-operating according to a programme proposed by Sweden at the last meeting of the International Council before the War. Observations made simultaneously from these anchored ships led to important results, published by Dr. B. Kullenberg of this Institute in co-operation with Dr. I. Hela of the Havsforskningsinstitutet in Helsingfors[2]. Except close to the coast-line, rotating currents were found at all stations. At fifteen metres depth they had an amplitude of nearly 20 cm./sec. and, within the margin of experimental errors, the same phase. At two of the stations tidal currents of the M_2-period with an amplitude of 1–2 cm./sec. were discovered, the first record of tidal currents in the Baltic.

In the 'plankton-shaft' of the new Institute, which is twelve metres deep and two metres in diameter, large-scale plankton cultures under controlled conditions have been made with diatoms from the spring increase, a good crop of *Skeletonema costatum et al.* being obtained[3]. Afterwards a brood of copepods was kept alive for several weeks in the shaft. Unfortunately, Dr. Fabius Gross, who in the spring of 1939 arrived from Edinburgh to carry out these experiments together with Dr. F. Koczy, of this Institute, has been prevented by the War from co-operating in the continued work. Attempts at 'manuring' the water of a small Swedish fjord, undertaken originally by the author some years before, have recently been resumed here in an enclosed bight particularly suited for the purpose. Excellent results from similar experiments made in Scotch lochs have in the meantime been reported by Dr. Gross and co-workers[4].

Research on the vitamin content in marine phytoplankton by the author has been continued in co-operation with the State Institute of Publ Health in Stockholm, where the biological analyse for vitamin D have been made. From large catche of diatoms collected during the spring increase weighing up to 80 kgm. in a wet condition, the fat soluble substances have been extracted and tested for antirachitic vitamins with and without previous irradiation by ultra-violet light. Whereas experiment with non-irradiated plankton and extracts gave indefinite results, the extracted oil, after exposure to ultra-violet light, gave variable but fairly large yield of vitamin D; in one case a maximum of 2,800 I.U. per gram of the oil was found. This implies tha there are fair amounts of the provitamin, probably 7-dehydrocholesterol, present in the diatoms. Separate tests with chickens are now being made in orde to ascertain whether the active substance is vitamin D_2 or not. The conversion of the provitamin into the vitamin by submarine daylight must remain a subjec for further research.

The last-named results give an enhanced interest to the short-wave components of submarine daylight and their possible importance for the ecology of the sea Dr. N. G. Johnsson at Bornö Station has at the author's request carried out measurements on the intensity of the antirachitic rays in the waters of the Gullmar Fjord, using rectifying selenium cells deprived of their lacquer coating and exposed behind liquid filters enclosed within hemispherical quartz walls. Consistent results proving the presence of antirachitic rays of wave-lengths between 3,000 A. and 3,200 A. were found immediately beneath the surface, the rate of extinction in fairly clear sea water being about 35 per cent per decimetre, so that already in a depth of one metre the intensity is reduced to between 1 and 2 per cent of its surface value. These results, apparently the first obtained with submarine ultra-violet light, have been confirmed by biological tests, in which preparations of 7-dehydro-cholesterol were exposed to sub-surface light behind transparent quartz disks at depths varying between 5 cm. and 1·5 metres.

Shortly before the outbreak of the War, at the request of the International Council, the work on the standardization of rectifying cells used for submarine photometry was transferred from Copenhagen to the Oceanografiska Institutet in Göteborg. In collaboration with Mr. H. Olsson of the Meteorological Office in Stockholm, Dr. Johnsson has worked out a practical method[5] for standardizing the cells by means of sunlight, as originally proposed by Dr. A. Ångstrøm. More recently, Kullenberg and Johnsson have been able to work out a simple method for converting the photo-current readings of submarine daylight into energy-values by means of conversion factors, suited to different conditions of surface illumination and of water transparency. Except in the very uppermost layers, less than 1 metre thick, where deviations due to infra-red radiation, etc., are somewhat larger, the results are assumed to be accurate to a degree corresponding to an error of only 0·25 metre in the depth, which is quite satisfactory for biological as well as for most geophysical purposes. Future light-measurements from oceanographic cruises and stations will become much simplified and the results comparable *inter se* thanks to this method. A standard transparency meter for sub-surface measurements has been constructed by Dr. Johnsson[6].

Work by the author and Kullenberg on improved core-samplers for marine sediments has made satisfactory progress[7], the longest cores hitherto obtained aving a length of nearly eighteen metres. This new echnique will have to undergo severe tests in much reater depths than those at present accessible (240 etres) before it can be recommended for deep-sea ork. Cores with perfectly undisturbed varves from the stuary of Indalsälven, Gulf of Bothnia, have been obained by one of the new core-samplers by Kullenberg[8].

Measurements of the radium content of deep-sea eposits and of manganese nodules from the *Chalnger*, the Monaco and Agassiz collections have been ade by the author[9]. The fall-off in radium content ith the depth below the nodule surface indicates a ate of growth of about 1 mm. in a thousand years r manganese nodules from the Pacific Ocean, an ncreased rate of growth in an upward direction eing interpreted as probably due to sedimentation t the rate of 0·5 mm. in a thousand years. The eautifully regular decrease in radium content with epth below the sediment surface, found by Piggot nd Urry in long cores from the Atlantic Ocean[10], eems to confirm the suggestion offered by the author n 1937[11], that a precipitation of ionium together with erric hydroxide occurs in the ocean and gives rise o part of the radium entering into the sediment, at he same time depleting the ocean water by about 0 per cent of the radium, which would correspond o its uranium content, about $1{\cdot}3 \times 10^{-6}\ {}^{0}/_{00}$ according o B. Karlik[12]. From measurements of thorium in he red clay, made here by Dr. F. Koczy, it can be nferred that thorium also has been very thoroughly xtracted from the water by the same *Mitreissreaktion*, the thorium content in the water being less than $0{\cdot}5 \times 10^{-8}\ {}^{0}/_{00}$, as compared with an earlier value for the upper limit of $0{\cdot}5 \times 10^{-6}\ {}^{0}/_{00}$ found by E. Foyn and E. Rona[13].

A special study of the manganese and iron present in deep-sea sediments, made by the author[14], provides important evidence against the hypothesis of a biological extraction from the sea water of these elements and their subsequent deposition on the bottom together with the foraminiferic shells, recently revived by W. Correns[15]. On the other hand, an extraction of the manganese present in the water through adsorption on very fine particles of volcanic ash, settling slowly through the water, does not appear improbable. The very pronounced local variations in the iron and, especially, in the manganese content of deep-sea sediments may be due to submarine volcanism, the deep-seated magma ejected over the ocean floor being presumably richer in manganese than continental basalts. The same agency, submarine volcanism, the author also holds to be at least partly responsible for the disappearance of the calcium carbonate from the red clay, due to mineral acids released in the reaction between the hot magma and the bottom water. If cold bottom water were the only lime-dissolving agency there ought to be no red clay below 1 or 2 metres from the sediment surface, owing to the higher temperature during the Tertiary age; a conclusion open to future tests by means of the new core-sampling devices.

CERATIUM AND MARINE HYDROGRAPHY

THE recognized importance of the study of plankton distribution in relation to marine hydrography has called forth a number of intensive investigations in recent years. Three reports* dealing with the distribution of the dinoflagellate genus *Ceratium* are of special interest in this connexion owing to the widespread representation of this genus in all oceans. The important conclusions reached by Graham and Bronikovsky from the examination of the *Ceratium* material gathered during the last cruise of the *Carnegie* in 1928–29 are briefly summarized in the following paragraphs. The survey deals not only with wide areas of the Pacific, but also with the North Atlantic; and, on the basis of the *Ceratium* floras, five regions are distinguished, namely, cold North Atlantic, warm Atlantic, cold North Pacific, warm Pacific and south-east Pacific. These regions are also characterized hydrographically.

Among the factors determining the horizontal distribution of *Ceratium*, temperature plays a foremost part. Apart from a few cosmopolitan (for example, *C. fusus*, *C. horridum*) and subpolar species (for example, *C. arcticum*, *C. lineatum*), the bulk are regarded as tropical. The latter are, however, grouped as species intolerant of colder water and rather closely confined to surface temperatures of 19° C. and above (for example, *C. breve*, *C. lunula*), as slightly tolerant of colder water (for example, *C. contortum*) and as very tolerant tropical species, such as *C. massiliense* and *C. hexacanthum* (*cf.* below). In the opinion of the authors there are no species distinctive of temperate latitudes, such being populated by tolerant tropical and cosmopolitan, with occasional sub-polar, forms.

The influence of the amount of nutritive salts (based on phosphate-determinations) is less easily assessed. Regions of very low phosphate content (for example, the warm Atlantic) are in general characterized by a scanty *Ceratium* flora comprising a large number of species, while those with a high content (for example, the North Atlantic and the North Pacific) tend to be more densely populated by a restricted number of species. There is, however, no exact correlation, and the authors conclude that the phosphate-content has no considerable effect on the horizontal distribution of the species of *Ceratium*, although in a given area relative values may be of some significance. Nielsen's view that the concentration of organic products derived from the plankton is an important factor in determining the distribution of *Ceratium*, a view based principally on the distribution of neritic and oceanic forms, is briefly considered but no data for or against the theory are provided.

The probable value of species of *Ceratium* as current indicators could not be very fully assessed in a gross survey like that undertaken by the *Carnegie*. Currents displace both the flora and its environment, so that species can exist in regions which are unfavourable to them until, by mixing with the adjacent water, that of the current becomes unsuitable and the species disappears. Good examples of displacement by currents are furnished by the tolerant tropical species. Thus, the Gulf Stream carries *C. extensum* to the British Isles (surface temperatures 12·4° C.) and *C. hexacanthum* to Iceland (surface temperatures 8·9° C.), although elsewhere these two species are not found at temperatures below 14·9° and 18·9° C. respectively. It does not appear that the equatorial currents appreciably affect the distribution of species of *Ceratium*.

---

* Peters, N., "Die Bevölkerung des südatlantischen Ozeans mit Ceratien", Wiss. Ergebn. Deutsch. Atlant. Exped. *Meteor*, 1925–7, 12 (1932); Nielsen, E. S., "Untersuchungen über die V breitung, Biologie und Variation der Ceratien im Südlichen Stillen Ozean", *Dana* Report, No 4 (1934). Graham, H. W., and Bronikovsky, N., "The Genus *Ceratium* in the Pacific and North Atlantic Oceans", Scient. Res. Cruise VII *Carnegie* (1928–9), etc. Carnegie Instit. Washington, Publ. 565 (1944).

Comparison of the *Ceratium* floras of the two great oceans shows that only eight of the fifty-eight species recorded are restricted to one ocean only and that is always the Pacific. The species in question (*C. deflexum*, *C. bigelowii*, etc.) are either strictly tropical or only slightly tolerant of colder waters, and the seas around Cape Horn may form an impassable barrier to their extension into the Atlantic. Certain differences in the distribution of species common to the two oceans suggest that there may be greater differences between their *Ceratium* floras than is at present apparent. Thus, although the North Atlantic and the North Pacific resemble one another in the occurrence in both of the subpolar *C. lineatum* and *C. arcticum*, there are striking differences which suggest biological isolation. *C. pentagonum*, a species widespread in the tropical seas of both Oceans, is absent from the North Atlantic while represented in the North Pacific by the very divergent subspecies *pacificum*. Again *C. macroceros*, with the subspecies *gallicum* frequent in all warm-water regions, is represented in the North Atlantic by the sub-species *macroceros*, though lacking in the North Pacific.

Twenty of the recorded species (for example, *C. praelongum*, *C. tenue*) show an increase in frequency from the surface to 100 metres. Such species have thin cells crowded with chromatophores which also extend into the horns when these are present. On the whole there is considerable agreement between the *Carnegie* data and those of Nielsen as regards these 'shade' species. The authors of the *Carnegie* Report, however, suggest that, apart from attunement to shade conditions, such forms may tend to move into layers of the water with a richer supply of nitrates and phosphates than are to be found in the surface layers at times of high plankton production.

F. E. FRITSCH.

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

THE forty-third annual report of the Carnegie Trust for the Universities of Scotland covers the academic year 1943–44, and includes a summary of the interim distribution of grants for the period October 1, 1943–September 30, 1944, with details of assistance to students and the abstract of financial accounts for the year ended September 30, 1944. In view of the continuation of war conditions, the Committee deemed it inexpedient to revert to the method of quinquennial distribution, and maintained the interim distribution on the same basis as previously. With regard to research, the situation was very similar to that recorded in 1942–43 and the abstract of accounts shows that a sum amounting to £15,497 has been accumulated, which is being held on behalf of fellows and scholars at present engaged on one or other form of national service, and of recipients of grants who have now been unable to make use of their awards. As it is unlikely that all those who have been awarded fellowships or scholarships since the outbreak of war will elect to begin or resum their researches under the ægis of the Trust, it possible that a substantial reserve will have bee created for the development of the Trust's plans fo aiding research.

The decline in the number of beneficiaries was mo marked in the Faculty of Arts where there were 1 less than in the previous session. The decline of in science on the figure for the previous session w more than offset by a sharp rise in the number beneficiaries in the Medical Faculty, the increase medicine being 80 over the previous year. It essential that it should be made known as widely possible that, unless in the future the number of th beneficiaries falls very considerably, the resources the disposal of the Trust will not permit any additio to the amount at present given by way of assistan in the several faculties.

The report on the work of investigators under th research schemes during the year referred to Mr E. M. Gorgeson's work on the flow of fluids through per forated tubes and through tubes the walls of whic offer little resistance to diametrical expansion. Tribut is paid to the achievements of Dr. Hwan-Wu-Peng i a new approach to the quantum theory of field Researches in geology, palæontology and geograph have been still more restricted, and during the perio scholars in chemistry, with few exceptions, held the scholarships in suspense pending a return to academ studies. Reference, however, is made to Mr. A. M Mathieson's work on the comparison of the structur of certain sulphur compounds, to Mr. A. C. Docherty' work on thermal diffusion in liquids and relate systems and to Mr. W. Graham's discovery of greatly improved method of obtaining a degradatio product of colchicin of primary importance in relation to the structure of this alkaloid, and hi synthesis of a new hydrocarbon with five condense benzene nuclei attained by fusing an additiona benzene ring on to the chrysene molecule.

In the Biological and Medical Sections reference i made to Dr. G. Pontecorvo's work on the behaviour of the chromosomes of the germ cells in securing transmission of the normal hereditary constitution, while yet providing for transmission of slight intrinsic variations of the genes, which afford the opportunity for the operation of natural selection and thus for the possible production of mutant forms. Dr. L. Auber continued to investigate the influence of physical and chemical factors upon the meal moth, and Mrs. C. M. Ritchie her investigations on carbohydrate metabolism in collaboration with Dr. H. W. Kosteritz. A list of publications by fellows and scholars and recipients of grants received from September 30, 1943, is appended.

The report of the Laboratory of the Royal College of Physicians, which includes some reference to Dr. Edith K. Dawson's investigations on the sarcoma of the breast and on another rare neoplastic condition. In the field of biochemistry under Dr. W. O. Kermack important progress has been made in the synthesis of various *o*-phenanthroline derivatives substituted in the 2-position by basic side-chains similar to those present in such active compounds as mepacrin or plasmoquin, and effort has now turned to the synthesis of *o*-phenanthrolines substituted in the 9 or 10 position. Mr. Jacomb has concentrated on the preparation of analogous compounds to give *p*-phenanthroline derivatives with a basic side-chain in position 9 or 10 on the benzene ring instead of in the 2-position. 9-Bromo-*p*-phenanthroline has been prepared and adily converted into amino-phenanthroline under nditions described by R. V. Haworth and W. O. kes. Before Mr. Dobson left the laboratory at the d of September, he had made excellent progress in e synthesis of pyridoacridine derivatives carrying sic side-chains of various types, some of which had ven very promising results on biological tests. Some ogress had been made in the related group of the nzacridines, some of which are also active. The rk on the pyridoacridines is being continued by r. Hutchison, who has concentrated on the synthesis compounds with various substituents in the icleus. Further evidence has been obtained of the rrectness of the assigned structure of the 4-hydroxy- -phenanthroline synthesized by Dr. Tebrich. Dr. ggleton and Dr. Kermack have also continued their athematical work on problems of diffusion such as e encountered in connexion with the diffusion of mpounds into and out of the tissues, and under Dr. evinthal experimental work for the development of general bacteriological medium is being pursued.

UNIVERSITIES AND THE NEEDS OF THE COMMUNITY

UNDER the title "Some Comparisons between Universities", the proceedings of the Second ducation Conference of the Association of University rofessors and Lecturers of the Allied Countries in reat Britain have now been published*. The report icludes a summary of the proceedings by Prof. R. D. aurie and a foreword by Sir Ernest Barker which mphasizes the wide range of thought which was ooled at the Conference. None of the British niversities and none of the Western universities ave, as Prof. E. Vermeil noted in an address n "The University Spirit in Germany and in the Vestern Democracies", succumbed to the domination f a political dogma, and similarly, as Mr. Willard onnely reminded the Conference, American univer- ities were among the first in the United States to ee the inevitability of American participation in the vorld struggle for freedom.

The report gives indeed an encouraging picture of he influence of the university on society which should be remembered when we are considering some current riticism of the universities. Mr. Connely can ightly point to such presidents of American niversities as Lowell and J. B. Conant, who ontended that universities must counteract rather than copy the defects of contemporary civilization, and have helped to make the American university a main instrument of fostering an international outlook. Sir Ernest Barker too refers to the strength which we can draw in facing the future from looking back on the past achievements of our universities and their contribution to religious life and national culture. The tradition of unselfish learning and the inheritance of national culture, which the ancient universities of Europe have steadily sought to accumulate and transmit from generation to generation, will be sorely needed as we face the task of reconstructing European society, and whatever changes or developments may be called for should not be such as to weaken that tradition or the love of learning, the passion for research and for teaching which have flowered in that old, rich and deep soil.

That the comparisons between universities made in this report leave first of all a deep impression of common traditions and ideals does not necessarily invalidate certain criticisms and suggestions for improving contacts made at the Conference. Prof. Jean Timmermans, who remarked on some points in which British practice in the organization of scientific research might be adopted on the Continent, believes that the exchange of scientific publications between Great Britain and the Continent is on an insufficient scale, and suggested a wider distribution of European periodicals in British universities. He also believes that there is a tendency to insularity in British universities, and that contact with them before the War was difficult. It was necessary to approach each university separately, and from this point of view he welcomed the proposal for a university council contained in the recent report of the British Association's Committee on Post-War Education.

Contacts are not entirely lacking, but Prof. Timmermans' view should be duly noted in considering the re-organization of the universities of Britain and their development to meet the larger demands both for teaching and research which will be made upon them in the immediate future. So too should the important point made by Sir Fred Clarke, in speaking on "The University and the Teaching Profession", that a university is scarcely entitled to prepare students for any profession unless within its walls the problems of that profession are being systematically studied. The condition is reasonably well fulfilled for such professions as medicine and engineering; but it is only beginning to be fulfilled in that of teaching—or, it might be added, of law. Again, the university is above all the guardian of standards, standards both of teaching and of attainment, in students, and no point will require more careful watching in these immediate post-war years.

On some of the other points of criticism expressed at the Conference there was less general agreement, and the suggestion in Mr. Bruce Truscot's paper on "Contact with the Student Mind" that a wide gap exists between the professor or lecturer and the student was not supported either by Prof. R. D. Laurie, who presented the paper, or by Sir Ernest Barker or by others: Mr. S. Grzybowski, a student of the Polish Medical School in Edinburgh, for example, was impressed by the closeness of the relation between the professor and the students. While Mr. Truscot's suggestion for the improvement of contacts between the university and the school was not entirely acceptable, the Conference appeared to recognize that it is important to strengthen that contact as much as possible. Again, Prof. Vaucher thought that the Continental scholar would be most impressed by the tutorial system in the older universities of Britain and the supervisor system in the newer ones; and Mr. Grzybowski thought that the British system is better for the average student, whereas the system of many Continental universities gives a better chance to the best students.

The relative position of teaching and research in the universities was just touched upon at the Conference without going deep enough to add anything to the present debate. Mr. Grzybowski thought that it is more commonly recognized in Britain than in some Continental universities that much the most important duty of the university staff is teaching.

---

* Association of University Professors and Lecturers of the Allied Countries in Great Britain., Second Education Conference, April 15, 1944: Some Comparisons between Universities Pp xvi+64. (Oxford: Basil Blackwell, 1944) 2s. 6d. net.

On the whole, it must be admitted that the four papers contributed at the session on research, apart from Prof. Timmermans' appeal for fuller exchange of scientific publications, and Prof. G. I. Finch's plea for British assistance to universities and research schools on the Continent in the form of interchange of apparatus and workers and teachers as well as literature, contributed little fresh. Dr. M. Ruhemann, in a paper on the organization of research in the U.S.S.R., while urging that organization is only a means to an end, never an end in itself, believes that some combination of a political, an economic and a scientific body is fundamental in order that research may be organized effectively on a national scale. To organize science without taking into consideration the economic needs of the country would lead to a divorce of science from the life of the people, and thus to a lifeless and scholastic science, while the organization of national economy without some political directive might be impossible.

More vital, on the whole, than the sessions on research and on teaching in the universities were those concerned with the influence of the university on the student and the influence of the universities on society. In the former, Miss M. R. Gale, secretary of the International Council of Students in Great Britain, and of the National Union of Students, stated that the students' union is a most important factor in training students in committee work, public speaking, and similar activities fitting them to take part in public life. Some Continental speakers remarked on a distinct gap between the student body in Great Britain and the rest of the community. Mr. J. L. Henderson, general secretary to the British Committee of World Student Relief, in speaking of what is already being done in this field of student relief and of the plans of the British Committee of World Student Relief for developing post-war activities, indicated at the same time one way of re-integration of student life with that of the community. He foresees during the post-war years a tendency among students to political apathy, frivolous irresponsibility, as well as to hatred and despair, especially among those who can appreciate most clearly the inadequacy of the political conditions which surround them. To rekindle the flame of true scholarship, to re-create moral values and spiritual principles may perhaps be done best by working empirically from the bonds which necessity in the shape of famine and disease has forged between all sorts of men holding all sorts of rival opinions. The immediate need in centres such as Vienna, Prague, Warsaw or Belgrade will be the establishment of student committees of self-help to plan and control, in association with whatever foreign assistance may be available, the relief work among local university students.

Mr. Henderson's plea for an act of imagination and faith, to restore student life to a worthy place in the community, was in keeping with the high note that was generally struck at the Conference. There was no disposition to ignore the fact that the Western universities have enemies. They were clearly enunciated by Prof. E. Vermeil as specialization, mechanization of learning and undue interference by the State; and Prof. Vermeil developed something of the argument of Mr. A. S. Nash in his book on "The University in the Modern World" which appeared after the Conference. The Western tradition of humanism, resting on the Greco-Latin humanities, on certain elements in Christianity, on the liberalism of the eighteenth century and the social spirit of t nineteenth, has always regarded the university as t chosen soil for the unimpeded growth of scienti research and culture. But the plans for universi reform, for the shaping of Western universities that they may serve more effectively the needs to-day, will come to nothing unless they are bas on a renewed conception of the university spirit, general culture and its role in the democracies to-morrow.

No one would pretend that this Conference made fundamental contribution to the evolution of a n philosophy of the university, but it at least points some of the fundamental questions that have to faced, to some problems where practical action mig easily be taken. In such thinking, it is no sm matter to have this evidence that the problems university expansion and its relation to the needs the community, to which so much thought h already been given in Great Britain, are problems which the best minds of Western Europe and t United States have also been exercised, that t great traditions of university life are held in comm with them, and that from their experience also may draw both guidance and inspiration.

TUNAS OF THE PACIFIC*

FOUR species of *Tuna* play an important part the fisheries of California, Mexico and Centr America: the skipjack *Katsuwonus pelamis* (Lin æus), the yellowfin tuna *Neothunnus macropter* (Temminck and Schlegel), the albacore *Thunn germo* (Lacépède) and the bluefin tuna *Thunn thynnus* (Linnæus). The big-eyed tuna *Parathunn mebachi* (Kishinouye) was also investigated and con pared with the others. The present study was unde taken in March 1940, to determine the geographic range of these and the relationships between the and similar species occurring in the Central, Wester and Equatorial Pacific. This entailed a detaile anatomical treatment which will form a firm founda tion upon which investigations may be extended int lines more directly applicable to conservation.

The work has shown concerning the skipjack tha within the entire fishing area in the Eastern Pacif extending along the Central and North America coast-line from the equator to California and offshor to include all the outlying islands, there is but single species, and specimens from all these area are furthermore individually indistinguishable fron those obtained from Japan and the Hawaiia Islands.

In the case of the yellowfin tuna, again there i a single species throughout the fishing area, and thes fish are individually indistinguishable from th specimens obtained from the Hawaiian Islands, Japa and Peru. Distinct populations may exist within thi larger area, but conclusions concerning these awai the analysis of data collected.

The albacore of the North American coast-lin proved to be the same species as that from Japa and the Hawaiian Islands, with a geographical dis tribution extending across the north temperat Pacific.

---

* A Systematic Study of the Pacific Tunas. By H. C. Godsil an Robert D. Byers. (Bureau of Marine Fisheries, California Division o Fish and Game · State of California Department of Natural Resources Division of Fish and Game, Fish Bulletin No. 60.) (Sacramento California State Printing Office, 1944.)

he bluefin tuna from southern and lower California essentially one species and, until adequate de- ptions are available from all localities, must be gned to the same species as *Thunnus thynnus* of Atlantic. Lacking material from Japan, com- ison with Kishinouye's (1923) description of *nnus orientalis* (the oriental bluefin) shows that is probably a different species.

Vith regard to the chief morphological features, it found that the appearance of the viscera ***in situ*** valuable identifying character. Other differences ear in the presence or absence of air bladder, erences in excretory system, and the circulatory tem which is unique in many respects. The differ- es in circulatory system were used by Kishinouye classifying the tunas. The present observations re confined largely, but not exclusively, to the erial system. The post-cardinal vein is present in but the genus *Thunnus*, but its course and degree development differ. The skeletal elements are arkably alike, and the authors believe that they r less promise for specific identification than other tomical parts. Nevertheless a key is given to five species studied, based on these skeletal ments; also a table giving a summary of tomical differences.

n the most important characters the skipjack fers from all the others. Alone it can be distin- ished at once by the external features. It lacks air bladder. The intestine is not folded. The ntral view of the viscera ***in situ*** is distinctive and ferentiates it. In its blood system and excretory tem it differs sharply from the others. It is the iest to identify of the five species.

Foreseeing the necessity of a more detailed popula- n study of some species, a large number of both ternal and internal measurements and counts were ded to the routine. These are reserved for a future rk.

A METEORIC THEORY OF THE ORIGIN OF THE EARTH AND PLANETS

D. J. SCHMIDT has a paper with this title in *Comptes Rendus* (*Doklady*) *de L'Académie des iences de L'URSS*. (**45**, No. 6; 1944), in which he opounds a new theory of the origin of the planetary stem. At the basis of the theory there are two ndamental facts—the rotation of the Galaxy and e presence near its central plane of large masses of oscuring matter. During its motion round the ntre of gravity of the Galaxy, the sun crossed a ark cloud of dust and meteorites and captured ortions of this, compelling the particles to revolve round its centre. In the course of time these cap- red particles united into larger formations, thus roducing the planets.

In a previous paper (*C.R. Acad. Sci. URSS.*, **44**, o. 1; 1944), the author dealt with the formation f binaries in a rotating Galaxy. The motions of tars are a combined result of the attraction of the entral galactic masses and of external masses and he neighbouring individual stars, and under certain onditions two stars can come into such a position hat they are drawn closer together, so that capture nd the formation of a double star occur. The ollowing assumptions, considered to correspond to tatistical averages, were made in dealing with this problem: (*a*) The stars move along circular orbits, subject to the attraction of the Galaxy, supposed to be concentrated in its centre. (*b*) The orbits lie in different planes inclined at small angles to one another. (*c*) Capture takes place when the two stars pass the position of the shortest distance between the orbits.

On these assumptions, a formula has been derived which connects the semi-major axis and eccentricity of the orbit of the binary with a quantity which depends on "the galactic parameter of the stars". This is a function of the distance to the galactic centre, the mass of the inner portion of the Galaxy, the total mass of the two stars, and the angle between the orbital planes of the stars previous to capture. While the formula is not strictly applicable in every case, as it considers mean results, nevertheless it is sufficiently accurate to apply to the problem of the capture of meteoric matter by the sun.

It is essential to the theory that the plane of the sun's galactic orbit should be inclined at an angle of about 3° to the central plane of the Galaxy. If the sun while at one of the nodes of its orbit passes through a cloud of matter, meteorites are captured in accordance with the same laws as underlie the formation of double stars. Both direct and retrograde motions take place with the captured meteorites; but if the sun passes near the edge of the cloud its density is not uniform, and in consequence more meteorites revolve in one direction about the sun. Those revolving in the opposite direction collide with the more numerous portion of the swarm and lose their momentum, ultimately falling into the sun. The main mass segregates in the course of time into larger bodies from which the planets are formed, and this segregation proceeds through smaller particles falling on larger ones just as meteorites fall on the earth at present. As the swarm of meteorites has the form of a flat lens, the planets in the process of formation have their orbits lying approximately in one plane—the central plane of the lens—and as the meteorites ultimately revolve in one direction, for reasons already suggested, the planets will also revolve in one direction. In the early stage the major axes of the swarm have a tendency to distribute their axes along the shortest distance between the galactic orbit of the sun and that of the cloud, but they are deflected from this direction by mutual perturbations. Hence no planet formed in the manner suggested can have a preferential direction for its major axis.

The problem of the angular momenta of the planets, which has been an insuperable difficulty with many theories of the formation of the solar system, is avoided by the present view, as the galactic momentum of the meteorites supplies the necessary angular momenta. Dr. Schmidt hopes that the theory will be further developed to bring within its scope such problems as the rotation of the sun and of the planets, the age of the planetary system, the formation of the satellites, etc. In addition, certain features concerning the internal structure of the earth are explicable, and Dr. Schmidt is engaged in the preparation of papers which will discuss such problems. The present paper contains some quantitative results regarding the distribution of mass and momentum in the planetary system and also the extent of agreement between the theory and observational evidence. These are largely provisional, and additional evidence in support of the theory will be forthcoming in the papers which are to be published in due course.

FORTHCOMING EVENT

Tuesday, August 14

Quekett Microscopical Club (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Conversation and the Exhibition of Specimens.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Irrigation Engineers for the Directorate-General of Irrigation, Iraq—The Ministry of Labour and National Service, Appointments Department A.9, Room 670, York House, Kingsway, London, W.C.2, quoting E.1817.A (August 17).

Technical Superintendent of the Blackburn Electricity Undertaking—The Engineer and Manager, Electricity Offices, Jubilee Street, Blackburn (August 18).

Lecturer in Mathematics, and a Lecturer in Natural Philosophy in the United College, St. Andrews—The Secretary, The University, St. Andrews (August 18).

Provincial Advisory Chemist in the Department of Agriculture and Horticulture—The Secretary and Registrar The University, Bristol (August 18).

Lecturer in Mechanical Engineering—The Registrar, College of Technology, Manchester 1 (August 20).

Assistant Master to take Physics and Chemistry—The Principal, Enfield Technical College, Queensway, Enfield, Middx. (August 20).

Lecturer in Chemistry at the Widnes Municipal Technical College—The Divisional Education Officer, Town Hall, Widnes, Lancs. (August 24).

Technical Assistant in Agricultural Economics—The Acting Registrar, The University, Leeds (August 24).

Borough Electrical Engineer and Manager—The Town Clerk, Municipal Offices, Grimsby, endorsed 'Borough Electrical Engineer and Manager' (August 24).

Gas Research Fellowship of the Institution of Gas Engineers tenable at the University of Leeds—The Assistant Clerk to the Senate, The University, Leeds (August 25)

Deputy Borough Engineer and Surveyor—The Town Clerk, Town Hall, East Ham, London, E 6 (August 25)

Assistant Lecturer in International Relations—The Secretary, London School of Economics, Houghton Street, Aldwych, London, W.C.2 (August 27).

Lecturer in Biochemistry, an Assistant Lecturer in Biochemistry, and a Demonstrator in Physiology—The Acting Registrar, The University, Leeds 2 (August 27).

Deputy General Manager and Engineer to the Sheffield Corporation Electricity Department—The Town Clerk, Town Hall, Sheffield 1 (August 28).

Assistant Engineer to the Nigerian Electric Supply Corporation, Ltd.—The Ministry of Labour and National Service, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting D 1297.XA (August 29).

Assistant Lecturer and Demonstrator in Engineering—The Registrar, University College, Cathays Park, Cardiff (August 30).

Lecturer in Agricultural Economics, and an Assistant Lecturer in Agriculture, at the Essex Institute of Agriculture, Writtle, near Chelmsford—The Chief Education Officer, County Offices, Chelmsford (August 31).

Probationary Assistant Lecturer in Economics (specially qualified in Statistics)—The Acting Registrar, University College of North Wales, Bangor (August 31).

County Organizer of Young Farmers' Clubs—The Acting Secretary, North Riding Federation of Young Farmers' Clubs, The Court House, Northallerton, Yorks (August 31).

Research Physicist, Division of Radiophysics, Sydney—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W C.2 (August 31).

Editor of the publications of the Chemical Society—The Hon. Secretaries, Chemical Society, Burlington House, Piccadilly, London, W.1 (September 3).

Registrar—The Registrar, University Registry, Cathays Park, Cardiff (September 8).

Professor of Aerodynamics, a Professor of Aircraft Structures, Engineering and Design, and a Professor of Engines and Systems of Propulsion—The Secretary to the Board of Governors, College of Aeronautics, 14 Belgrave Square, London, S.W.1 (September 15).

Registrar, and an Assistant Registrar and Bursar—The Secretary to the Board of Governors, College of Aeronautics, 14 Belgrave Square, London, S.W.1 (September 15).

Lecturer in Geography, and a Lecturer in Zoology, in the Natal University College, Pietermaritzburg—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 15).

Lecturer (specially interested in Physical Metallurgy) in the Department of Metallurgy—The Registrar, The University, Sheffield (September 15).

Lecturer in Mathematics—The Secretary, Queen's University, Belfast (September 30).

Master of Method and Lecturer in Science and Mathematics at the Edinburgh Training Centre (Moray House)—The Executive Officer, 140 Princes Street, Edinburgh (October 10).

Lecturer in Inorganic and Analytical Chemistry—The Secretary, The University, Aberdeen (October 15).

Chair of Metallurgy tenable at the Imperial College of Science and Technology—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (October 31).

Librarian of Auckland University College, Auckland, New land—The Secretary, Universities Bureau of the British Em c/o University College, Gower Street, London, W.C.1 (December 1

Technical Assistant—Chief Engineer, Newcastle and Di Electric Lighting Co., Ltd., 81 Westgate Road, Newcastle-upon-T

Area Supervisor (home-based, to live in the Newport, Shrops area), and an Assistant Area Supervisor (to live in the War area), under the National Milk Testing and Advisory Scheme—Principal, Harper Adams Agricultural College, Newport, Shrops.

Assistants (male) for Petroleum Laboratory work and operation of small experimental plants on shifts—The Ministr Labour and National Service, Appointments Department, Sar Street, Kingsway, London, W.C.2, quoting Q.N.410.

Indexer and Abstractor of technical publications in the Mi Resources Department—The Establishment Officer, Imperial Insti South Kensington, London, S.W.7

Lecturer in Inorganic and Physical (Pharmaceuti Chemistry—Prof. W. H. Linnell, College of the Pharmaceu Society, 17 Bloomsbury Square, London, W.C.1.

Radium Custodian (woman)—The Clerk to the Governors, Bartholomew's Hospital, London, E C.1.

Forester (practical, experienced, working) for the Isle of M The Secretary, Isle of Man Forestry Board, Atholl Street, Dou Isle of Man.

Assistant Lecturers (temporary) in Zoology—The Secret University College, Gower Street, London, W.C.1.

Teacher (well qualified) of Chemistry and General Scien The Principal, Technical Institute, Tunbridge Wells.

Lecturer in Mechanical Engineering—The Secretary, W wich Polytechnic, Woolwich, London, S E 18.

Teacher of Engineering Subjects, and a Workshop Instruc in the Harrogate Technical Institute—The Municipal Officer, Ha gate.

Lecturer in Hygiene and Applied Science—The Princ Normal College, Bangor, North Wales.

THE END OF THE SECOND WORLD WAR

THE dramatic collapse of Japan under the pressure of unprecedented air bombardment accompanied by the threat of invasion by overwhelming forces marks the end of the War of 1939–45—the Second World War. More than that, it marks the end of a period extending over some thirty-five years which has witnessed increasing social unrest and suffering, culminating in warfare of an intensity never before witnessed, and physical destruction on an appalling scale. War has now become so terrible, so swift in its march and so indiscriminate in its cutting off of old and young alike, that the greater nations of the world must recoil with horror from the possibility of another major war, lest they court annihilation of whole populations. This is not to say that armed forces will be unnecessary; for so long as man falls short of the ideal in his ethical outlook and practice, there will be differences and disputes, some of which may lead to wars. But it should not be beyond the power of the nations, imperfect as man is, to limit the conflict and promote a swift settlement. Towards this end the United Nations Charter is a first instrument, based on a mixture of idealism and worldly practicability, which can be of prime importance for the future of humanity.

Two events of the immediate past will always be associated with the surrender of Japan to the will of the United Nations. These are the use of atomic energy in the form of a bomb of stupendous destructive power, and the declaration of war on Japan by the U.S.S.R. It is idle to speculate on their relative significance, in that both are the result of carefully prepared plans carried out over a long period; and the fact that they came to fruition almost simultaneously may have been a coincidence. In any event, we are more concerned for the moment with the significance of the release of atomic energy in manageable fashion. This, as we have already pointed out (*Nature*, August 11, p. 153), is a landmark in the history of mankind—it marks the beginning of a new era, an era in which the quality of the work of men of science of the world will not only be of immense importance, but will also be acknowledged as such. It is not suggested that men of science should become, as it were, a ruling caste, to whom all others would defer; they themselves would be the first to dispute any such intention, for their training does not of necessity develop the qualities needed for administration. Rather we would anticipate that they will be expected to take a share in the tasks of government, as they have done during the War, at the direct request of the ruling authority and with a conspicuous success which has been generally acknowledged and acclaimed. Gone, it is hoped, are the days when men of science were regarded as useful standbys, to be called in when things go wrong and speedily relegated to the background after use has been made of their knowledge. But scientific workers must also play their part; they must not allow their preoccupation with their particular interests to make them oblivious to their responsibilities as citizens of a world which is becoming increasingly dependent on their efforts, and they must maintain their high standard of integrity.

So far as the general outlook is concerned, the present position as regards scientific and industrial research is very little different from that at the close of hostilities in Europe (see *Nature*, May 12, p. 553). Everywhere throughout the world there are shortages due to sheer destruction, to lack of raw materials, to transport difficulties and so on. There are innumerable problems for men of science to tackle, arising out of war-time conditions; and in addition, there has been a space of six years during which scientific investigation has been very largely diverted from its normal course. Scientific workers will also be called upon in the immediate future in connexion with the control of Japanese scientific and industrial development.

This task will be much the same as in Germany; for Japan is highly industrialized, and the guidance of her industries on to peaceful lines will require equivalent measures. Nor need the difficulty of a language so different in form and structure from those of Western Europe be regarded as an insuperable barrier. Many educated Japanese are familiar with Western languages, and also there is a small number of European scholars who have studied Japanese history and culture and whose guidance will no doubt be sought; further, steps have already been taken to train students who show an aptitude for Oriental languages in readiness for such duties as may devolve upon an occupying body. So far as scientific and industrial processes are concerned, there will be little difficulty; the chemical equation has the same significance, both qualitative and quantitative, in the Far East as in the West, and there is no possibility of shades of meaning; mathematical symbols are equally definitive throughout the world, whether they are used in purely mathematical work or in connexion with aerodynamics, hydraulics, electrical engineering and other applied studies. Scientific research and industrial practices in Japan have come mainly from European and North American sources and employ the same terms and even the same symbols. Thus it is quite common to find a scientific paper written in Japanese but liberally sprinkled with chemical equations printed in Latin characters with Arabic numerals just as in European practice. Even in biology and geology, scientific terms are usually employed directly without translation, and the binomial system of nomenclature of living organisms is as apparent in papers in Japanese on biological topics as are the chemical equations referred to above. Indeed, the language of science, as it is written in Europe and America, is truly international in form and significance.

In devising means of controlling scientific research and industrial and engineering development in Japan, there seems no reason, as has been suggested above, why it should not follow the main lines laid down for the control of Germany, but with the important proviso that policy will be influenced by the counsel of those who are familiar with the Japanese mode of life and cultural tradition. It would be absurd to attempt control of a country like Japan, which, in spite of the veneer of twentieth centu industrialization presented to the casual observer, steeped in a tradition wholly alien to the outlook Western Europe and North America, withou adequate consideration of these factors.

So much for one specific problem posed by th control of Japan. The distance separating th country from Western centres will present difficulti for the maintenance of even a token occupatio force, both as regards supplies and the morale of th men; and numerous other points for anxious decisio must arise.

Many such matters must be regarded as involvin what has been termed the tactics of science. W must now revert to the broader question of th grand strategy of scientific and technical developmen The controlled release of atomic energy applied i the development of the atomic bomb emphasizes onc more the importance of scientific research, and i significance for the progress of knowledge and for th material welfare of mankind. Scientific and technica research has made possible this appalling weapon o destruction, and it will not let the matter rest ther As was pointed out in *Nature* of August 11, the discovery is the culmination of many years of patien and sometimes dangerous investigations, and the fac that it has been developed for the purpose of war i no fault or desire of scientific men as a body. They will therefore wish to push on vigorously with investigations of the mechanism of the reaction involved, and with their adaptation to the peace-tim needs of man. This may mean many years of labou —perhaps as many as have passed since the idea o atomic disintegration became more than the philosopher's dream. But they will not be deterred.

Nevertheless, means must be found of financing such investigations, which from their very nature can claim the interest only of those concerned with long-range developments; and present indications are that much elaborate and costly equipment on an engineering scale will be necessary. Only Governments or national institutions are likely to be in a position to respond to the requirements of research of this character in atomic physics. All this points towards the same conclusion as was reached in considering the moral aspects of the discovery of the regulated release of atomic energy, namely, it is a responsibility of Governments. The possibilities for good or evil are of such magnitude that individuals cannot fairly be entrusted with their exploration; similarly, none but Governments are likely to be able to provide the continuous expenditure necessary for development. Moreover, there must not be parsimony in the matter, as so often occurs when results do not immediately accrue; there must be faith in the outcome even when times are difficult and retrenchment seems inevitable. President Truman's request to Congress for provision for such research, and the British Government's announcement of its desire for collaboration, are therefore welcome moves; the Canadian Government is also to push on with investigations. The keynote in this matter, as in other affairs, is research, and yet more research. Research can be speeded up in time of national emergency, as we have recently seen, and now it is a matter of world emergency. Coupled with research there must be education, in the broadest sense, as has often been emphasized in these columns, so that nations may appreciate their responsibilities to their neighbours, who are now all the peoples of the world.

But we would conclude on a note of hope for the future. The end of the war with Japan marks the total defeat of aggression in the East and the West. To achieve it the freedom-loving nations have combined their forces, and incidentally voluntarily surrendered much of their freedom as sovereign States, while individual men and women have submitted to government largely by order from higher authority. It is not desirable or possible that such loss of democratic rights and privileges should continue; but it should be quite clear that the active association of the Great Powers must go on, in order that the world may recover from the disaster which has overtaken it. The United Nations Charter is a first step in this direction, on which it must be hoped that the nations of the world will build a structure enabling mankind to go forward in peace and prosperity to a new world order.

JOHN TYNDALL

Life and Work of John Tyndall

By A. S. Eve and C. H. Creasey. Pp. xxxii+404+25 plates. (London: Macmillan and Co., Ltd., 1945.) 21*s*. net.

JOHN TYNDALL was among the greatest masters of experimental demonstration that the world has seen. Davy, Faraday, Dewar and Bragg stood high in this category, and it is noteworthy that all these prepared and produced many of their demonstrations at the Royal Institution. In this particular direction Tyndall stood as high as any of them. It is not easy to realize how much of what is now the commonplace of lecture illustration in the physical sciences became so through him. He gave much thought and study to producing dramatic effects; indeed, stories were current which caricatured this aspect of his lectures, though it is difficult at this distance of time to judge whether any credence should be given to them. However that may be, there can be no doubt about the eagerness with which he was listened to, both in Great Britain and in the United States, nor about his great skill in carrying a popular audience with him.

The picture has, of course, another side. Some scientific men, among whom P. G. Tait was conspicuous, seem to have been much irritated by Tyndall's popular reputation, and hinted more clearly than good manners should have permitted that he verged on being a charlatan. I have looked over several of his books to try and judge for myself whether there was any real justification for this, but I cannot find that there was any.

Though I can remember Tyndall in the flesh, I was too young at the time to form any judgment of my own. The late Lord Rayleigh, however, who knew him well, thought highly of Tyndall's scientific work, and expressed himself more emphatically than was usual with him in the sense that Tyndall's critics were entirely mistaken in their estimate. He thought, however, that they had had their effect on Tyndall by putting him on the defensive.

The controversy about the doctrine of energy was one of the points on which Tait was most emphatic. It is not doubtful, I believe, that J. B. Mayer was the first to give a numerical value for the mechanical equivalent of heat, and that his value was substantially correct. If these facts are admitted (and I have not seen them denied), the plain man will not easily be convinced that Mayer's contribution was worthless. Yet Tait and also Kelvin were inclined to take this line. There was no doubt a serious flaw in Mayer's argument; but it may well be held that those who enunciate new and important results *which prove to be right in substance* should not be judged by the criteria which would be appropriate in marking an elementary examination paper a generation later. Tyndall, moved by a sense of justice, argued strongly in Mayer's favour, and I believe that the view which he took has been generally adopted in Germany; Helmholtz at least seems to favour it. Tait was probably right in assuming that Tyndall knew little of the more abstruse questions of mathematical physics: but it is not apparent that he ever professed to do so, and, after all, one cannot do everything. Tyndall, in spite of ill-health, and with no initial advantages, achieved a great deal for science in many directions. We should be grateful for what he was, rather than critical of what he was not. This book fills, at long last, a gap in the history of British science in general, and of the Royal Institution in particular.

The reviewer has read again, after an interval of more than fifty years, several of the essays contained in Tyndall's "Fragments of Science", and comes away with the impression that they have stood the test of time remarkably well. Phrases are occasionally met with which grate unpleasantly on the modern scientific ear, particularly where Tyndall deals with the electric arc, and the design of the dynamo; but if it is remembered that at the time the ampere and the volt had scarcely been defined, still less were any direct-reading instruments available for measuring currents and electromotive forces, this must in fairness be put down to the contemporary state of electrical science rather than to any shortcomings on the part of their author. By reading rather out-of-date accounts of scientific advances, one gets an insight into where the difficulty lay which is of great historical interest, and which fills a gap which can scarcely be filled otherwise. It is not at all easy for any student of scientific history to appreciate a difficulty which is no longer felt. In this matter of the efficiency of the dynamo, Tyndall's generation certainly felt at the back of their minds that there was some inherent obstacle to its working at a high efficiency. There is, of course, in fact no such obstacle, and it is very hard now to trace why they thought that there was. It is not suggested that Tyndall particularly countenanced this idea, though in some passages he seems to attach a theoretical importance to the internal resistance of the machine which reads oddly to-day.

It is difficult, coming to another aspect of Tyndall's writings, at this distance of time and in the intellectual atmosphere of the present day, to understand the storm which was aroused by his Belfast address to the British Association in 1874. A profound effect was provoked by that address, and the passage which was most resented has often been quoted—it runs thus: "The impregnable position of science may be described in a few words. We claim, and shall wrest from theology the entire domain of cosmological theory. . . ." The almost equivalent statement that "The Bible was not meant to teach science" might now be heard without surprise from any evangelical pulpit.

There can now be few, if any, survivors of those who hung on Tyndall's words at the Royal Institution and who would have been the most eager readers of this book. A series of unfortunate circumstances led to its late appearance. Chief among these, it must be confessed, was the very dilatory way in which Mrs. Tyndall dealt with the materials which were in her hands. In theory it had been her aim to devote her life to erecting this memorial to his memory, and as she survived him for many years, living a quiet life in the country, it would not seem at first sight that the opportunity to carry out this purpose was lacking; but misfortune seems to have dogged the project. Mrs. Tyndall began with an exaggerated notion of the scale on which such a book should be written. She was not prepared to reject anything; and under these conditions the amount of material proved unmanageable. Further, when it became obvious that she would never complete the work, she would not reconcile herself to putting the material in other hands, or to parting with the detailed control of how it was to be used. The result was that nothing effective was done while Mrs. Tyndall was alive. She provided, however, for its being accomplished by others, and her nephew, Mr. Granville Proby, has seen to the ultimate and satisfactory fulfilment of her wishes. He placed it in the hands of Prof. A. S. Eve, the biographer of Lord Rutherford, and when Eve was unable to continue, it was finally finished by Mr. C. H. Creasey.

As the result of this long delay, the book will not now be read by those whose personal memories would have illuminated the subject, but the story has at least been satisfactorily recorded for the present and future generations. RAYLEIGH.

BESSEL FUNCTIONS

A Treatise on the Theory of Bessel Functions

By Prof. G. N. Watson. Second edition. Pp. viii+804. (Cambridge: At the University Press, 1944.) 60*s*. net.

THE memoir in which Bessel, the astronomer, examined in detail the functions which now bear his name was published in 1824, and was the outcome of his earlier researches concerning the expression of the radius vector in planetary motion.

The ordinary linear differential equation of the second order

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} + (x^2 - \nu^2)\,y = 0 \quad . \quad . \quad (1)$$

is known as Bessel's equation of order ν. Any solution of this equation is a Bessel function of order ν. Neither x nor ν is necessarily restricted to real values.

If in (1) we write $u = y\sqrt{x}$, the corresponding equation for u becomes

$$\frac{d^2u}{dx^2} = -\left(1 + \frac{\frac{1}{4} - \nu^2}{x^2}\right)u$$

which for large values of x tends to the simple harmonic equation

$$\frac{d^2u}{dx^2} = -u, \quad . \quad . \quad . \quad . \quad (2)$$

the solution of which is well known to be of th form $u = A\cos x + B\sin x$, so that for large value of x, any Bessel function y may be expected t behave like $(A\cos x + B\sin x)/\sqrt{x}$. Moreover, jus as the general solution of (2) is expressed in term of the familiar special solutions $\cos x$ and $\sin x$, s the general solution of (1) is expressed in terms o any two linearly independent special solutions, fo example, the particular Bessel functions denoted b $J_\nu(x)$, $Y_\nu(x)$ where

$$\begin{aligned} J_\nu(x) &= \sum_{m=0}^{\infty} \frac{(-1)^m\,(\frac{1}{2}x)^{\nu+2m}}{m!\,\Gamma(\nu+m+1)} \\ Y_\nu(x) &= \frac{J_\nu(x)\cos\nu\pi - J_{-\nu}(x)}{\sin\nu\pi} \end{aligned} \quad . \quad . \quad . \quad . \quad (3$$

When ν is an integer n, $Y_n(x)$ is defined as the lim of $Y_\nu(x)$ when $\nu \to n$. These functions are know as Bessel functions of the first and second kind respectively. For large values of x they approac the respective values

$$\left(\frac{2}{\pi x}\right)^{\frac{1}{2}}\cos(x - \tfrac{1}{2}\nu\pi - \tfrac{1}{4}\pi),\ \left(\frac{2}{\pi x}\right)^{\frac{1}{2}}\sin(x - \tfrac{1}{2}\nu\pi - \tfrac{1}{4}\pi),\ (4$$

and this parallelism with the cosine and sine is on of the three reasons which the author adduces fo adopting $Y_\nu(x)$ as the canonical function of th second kind. Moreover, just as the solutions cos $\sin x$ of (2) are connected by $\cos x = \int \sin x\,dx$, s we have the relation

$$Y_\nu(x) = \frac{2}{\pi}J_\nu(x)\int\frac{dx}{xJ_\nu^2(x)}$$

between the functions (3), a suitable value of th constant of integration being presumed in each cas The forms (4) also show how to obtain approximat values for the large zeros of the functions (3).

The zeros of Bessel functions are important bot for the theory and for the physical applications Let $j_1, j_2, \ldots$ denote the positive zeros of $J_\nu(x)$ i ascending order of magnitude. Then

$$\int_0^1 xJ_\nu(xj_r)\,J_\nu(xj_s)\,dx = \tfrac{1}{2}J_{\nu+1}(j_r)\,J_{\nu+1}(j_s)\,\delta^{rs}$$

where $\delta^{rs} = 0$ or 1 according as $r \neq s$ or $r = s$ This leads to the Fourier-Bessel expansion of a function $f(x)$, provided such an expansion is possible in the form

$$f(x) = A_1J_\nu(xj_1) + A_2J_\nu(xj_2) + \ldots$$

where

$$\tfrac{1}{2}A_rJ^2_{\nu+1}(j_r) = \int_0^1 xf(x)J_\nu(xj_r)\,dx,$$

a method entirely analogous to that of Fourier's expansion.

Of great importance in mathematical physics are the modified Bessel functions $I_\nu(x)$ and $K_\nu(x)$ whic are certain particular solutions of the equation whic arises from (1) when ix is written for x. Here, fo example, if x is real and positive

$$I_\nu(x) = e^{-\frac{1}{2}\nu\pi i}J_\nu(ix).$$

Kelvin's functions ber x and bei x, which hav applications in alternating current theory, are th real and imaginary parts of $I_0(x\sqrt{i})$.

In applied mathematics Bessel functions find thei use in a wide field, of which a few instances can b ited in general terms: in hydrodynamics, to wave motions, vortices, viscous flow; in electricity, to microphones, transmission lines, skin currents, waveguides; in elasticity, to isotropic rods, torsional vibrations; in mechanics, to cylindrical rods, vibration of membranes, oscillating chains. Indeed it was in connexion with this last problem that Daniel Bernoulli in 1738 actually obtained an infinite series which is the expansion of a Bessel function, and noted that it had an infinite number of zeros.

One reason at least will make clear why numerous physical applications are to be expected. Laplace's equation in cylindrical co-ordinates (r,θ,z) assumes the form

$$\frac{\partial^2 V}{\partial r^2} + \frac{1}{r}\frac{\partial V}{\partial r} + \frac{1}{r^2}\frac{\partial^2 V}{\partial \theta^2} + \frac{\partial^2 V}{\partial z^2} = 0.$$

If we seek to satisfy this by $V = \mathrm{R}\Theta\mathrm{Z}$, where R, Θ, Z are respectively functions of r, θ, z alone, we find that $\Theta = e^{\pm i\nu\theta}$, $\mathrm{Z} = e^{\pm ikz}$, and if $u = kr$,

$$u^2 \frac{d^2\mathrm{R}}{du^2} + u\frac{d\mathrm{R}}{du} + (u^2 - \nu^2)\,\mathrm{R} = 0,$$

which is Bessel's equation. Thus, Bessel functions play the same part in potential problems relating to cylindrical boundaries (for example, the flow of heat) as do Legendre's functions in problems relating to spherical boundaries.

In Prof. Watson's treatise, which is a monument of erudition and of its often too rare accompaniment, clear exposition, we have a rigorous mathematical treatment of all types of Bessel functions, their properties, integral representations, asymptotic expansions, integrals containing them, allied functions, series, zeros, tabulation, together with extensive numerical tables. To quote from the preface to the first edition, "The book has been designed with two objects in view. The first is the development of applications of the fundamental processes of the theory of functions of complex variables. . . . The second object is the compilation of a collection of results which would be of value to the increasing number of Mathematicians and Physicists who encounter Bessel functions in the course of their researches. . . . While my endeavour has been to give an account of the theory of Bessel functions which a Pure Mathematician would regard as fairly complete, I have consequently also endeavoured to include all formulæ, whether general or special, which, although without theoretical interest, are likely to be required in practical applications; and such results are given, so far as possible, in a form appropriate for these purposes." This was written in 1922, and apart from a few minor corrections, the second edition is a photo-reprint of the first, the author stating that he was unprepared to undertake the rewriting of about half the book to the detriment of other activities. With this view we may sympathize, but at the same time we must regret that Prof. Watson has not taken the opportunity to include at least one new chapter on the application of Heaviside's operational calculus or its equivalent, the Laplace transform, to Bessel function theory, which has been so largely developed in the intervening twenty years. His unrivalled powers of exposition would have made this a welcome addition. Nevertheless, the book is one which nobody interested in Bessel functions can afford to ignore, or should even wish to do so.

L. M. MILNE-THOMSON.

FAMILY STUDIES IN TUBERCULOSIS CONTROL

Familial Susceptibility to Tuberculosis

Its Importance as a Public Health Problem. By Dr. Ruth Rice Puffer. (Harvard University Monographs in Medicine and Public Health, No. 5.) Pp. xi+106. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1944.) 2 dollars.

THE author of this excellent little book is a member of the Williamson County Tuberculosis Study, Tennessee; her object is to assess the significance of two factors in the development of tuberculosis: first, familial susceptibility; second, exposure to infection.

A review of past and present literature amply shows that many writers regard the susceptibility of the individual—the 'soil' as it is often called—as a factor equal in importance with infection in the causation of tuberculosis. At the same time it is generally agreed that if the infecting dose is heavy individual susceptibility is of much less importance. It is pleasant to read again the call that Karl Pearson made for sober reflexion, when, after Koch's discovery of the tubercle bacillus, popular opinion swung violently over to infection as the chief cause of tuberculosis with resulting complete neglect of all other factors. We shall do well to remember the need for clear thinking at the present time when so many new discoveries are being made.

The author goes on to show that many regard familial susceptibility as a factor in the development of several other diseases; but it seems unnecessary in a book of this size to devote nearly a whole chapter to discussing this in relation to leprosy, rheumatic fever, poliomyelitis, and diabetes. There is a useful account and discussion of animal experiments that show evidence of familial susceptibility; these are obviously of great importance. But it is surprising, in so wide a review of the literature, that mention is not made of immunization against tuberculosis with living attenuated bacilli (B.C.G.). Wells's experiments on immunizing animals with vole acid-fast bacilli also deserve mention, especially since there has been a recent revival of interest in attempts to immunize actively against tuberculosis (leading article, *Brit. Med. J.*, p. 716; December 14, 1943).

In discussing the analysis of the data presented, the author stresses the need for a suitable tuberculosis classification such as Opie's, which is used. This classification is given in detail as an appendix to the book. Frost's statistical method ("person—years of life experience") as applied to morbidity- and mortality-rates is most suitable in work of this kind. Full details of this method, which is an adaptation of life table procedures, are given in an appendix to the book. There are many advantages in using the 'index case' instead of the 'primary case', the 'index case' being that of the individual whose medical history of known or suspected tuberculosis directs attention to his family or associates. Data from the Williamson County Study that concern siblings, consorts, parents, and children of 'index cases' are analysed and discussed in comparison with similar studies by other workers. Interesting work on twins is discussed, and figures are quoted to show that tuberculosis-rates are higher in the co-twin of uniovular twins than of binovular twins. But it must be remembered that uniovular twins are of the same sex and are as a rule very closely associated.

An interesting explanation is given for the decline of the tuberculosis death-rate: when the rate is high more females die than males; but as the rate falls the sexes are equally affected, as in England about 1860; thereafter the male death-rate begins to exceed the female. This, it is said, is due to the deaths of females during the child-bearing period and the result is a reduction of the number of susceptible families. This point is well worth remembering when assessing the value of control measures over a number of years.

More light is thrown on the vexed question of tuberculosis in consorts. It is known that a large proportion of exposed consorts do in fact develop the disease, but that others remain well. The family history of exposed consorts shows that those whose families are tuberculous show a higher incidence of the disease than those whose families are free from tuberculosis. It is emphasized that to know the true picture for children they must be followed up after they leave the home.

In a concise summary the author outlines how better methods of control could be instituted by a more comprehensive case-finding campaign based on information about those persons known to have tuberculosis and about susceptible families. Surprisingly, mass miniature radiography is not discussed; it is by this method above all others that much wider groups can now be examined than ever before.

Although it offers nothing outstanding in the way of new discoveries, this book succeeds in its aim of throwing more light on the problems of susceptibility to tuberculosis, and it includes a really remarkable amount of useful information in just over a hundred pages. The volume is well written and presented, the graphs and tables are clear and easy to understand, and a full bibliography is included. All concerned in the control of tuberculosis—public health officers, tuberculosis officers, health visitors, social workers general practitioners, and medical research workers —should find much to interest them in its pages.

THE CHILD'S BLOOD IN HEALTH AND DISEASE

Atlas of the Blood in Children

By Dr. Kenneth D. Blackfan and Dr. Louis K. Diamond. Pp. xiv+320 (70 plates). (New York: Commonwealth Fund; London: Oxford University Press, 1944.) 66*s*. 6*d*. net.

ALTHOUGH we have long been accustomed to coloured illustrations in text-books and monographs on hæmatology, we find in this "Atlas of the Blood in Children" something above the ordinary not only in its extent, but also and more especially in the happy combination of faultless artistry and perfect colour-printing. The very slight variation in colouring due to the routine use of Wright's stain in place of those more commonly used in Great Britain, namely, Leishman or Giemsa, does not detract in the slightest from the value of the seventy plates used to illustrate the important features of the blood pictures of more than five thousand cases examined and catalogued by the authors in their special hæmatological laboratory in the Infants' and Children's Hospitals, Boston. A special point is made of the fact that the "Atlas" is not intended as an exhaustive treatise on the variations in the blood in diseases of children, but represents only conditions with whic the authors have had close personal experienc This will explain some omissions, and also the appa ently undue stress laid on diseases seldom seen i Britain, such as Meditteranean anæmia and sickle ce anæmia.

The text deals with the hæmatology of childhoo in five main sections: the blood cells; anæmias; th leucocytes in disease; the leukæmias; the platelets The first section has much valuable information, bu will be spoilt for most British readers by its use o the term 'megaloblast' for the parent cell in th normal development of the red blood corpuscles Once the necessary mental adjustment has been mad to allow for this divergence from hæmatologica nomenclature in Britain, the rest of this, and of the succeeding section on the erythrocytes in anæmia, can be read with real pleasure and much profit. The authors have adopted a purely morphologica basis for the classification of the anæmias, which, though somewhat outdated, lends itself admirably to a treatise in which pictorial representation of the blood as seen in stained films is the *raison d'être* of the publication. The inclusion of a separate group of "Anaemias often associated with Jaundice", though inconsistent with this classification, has its points clinically.

The section on "The Leucocytes in Disease" has much valuable observation condensed in the few pages devoted to it. Particularly valuable are the full descriptions of significant blood pictures in pulmonary tuberculosis and infectious mononucleosis. In the section on leukæmia there is perhaps an over-elaboration of clinical types and too facile a dismissal of the value of marrow puncture. The last section, on the platelets, is adequate, but contains an inexplicable confusion between Henoch's and Schönlein's purpura. This lapse will certainly cause the authors no heart-burnings, since they rightly dismiss these subdivisions of purpura as of little real significance.

The "Atlas" and its text are obviously intended primarily for the practising pediatrician and his hæmatologist. Full case histories of selected illustrative examples of the various disease states are included but are not overdone. Commendable restraint is also exercised in the details of laboratory data, particularly in the matter of descriptions of the blood picture presented, the very realistic coloured plates of blood films taking the place of these descriptions. There is little attempt at discussion of debatable theories and hypotheses, and if this does at times result in the apparently uncritical acceptance of views still *sub judice*, it certainly leads to brevity. There is a healthy insistence on the practical in both treatment and investigation, and the dangers and advantages of blood transfusions receive frequent and carefully considered mention. The sequence of the illustrations follows that of the text, and each plate is faced by an outline drawing on which the characteristic or abnormal cells are numbered for detailed reference in the descriptive legends. The printing is excellent, the style easy and the indexing satisfying.

This joint production by the clinician, the laboratory hæmatologist and the artist is one which goes a long way towards filling a serious gap in the bookshelves of pediatricians and clinical pathologists, and can be warmly commended not only to these but also to all who have any contact with hæmatology in general or with children in any branch of medical practice. THOS. B. DAVIE.

A HITHERTO UNPUBLISHED LETTER OF ISAAC NEWTON

HE Royal Society recently received, on indefinite loan from its present owner, a hitherto unrecorded tograph letter of Isaac Newton. The letter is a ıg one, it has an intrinsic interest for the history science, it is in a remarkably good state of preserva- n and its authenticity is established with unusual mpleteness. It was written in 1677 from Cambridge the Hon. and Rev. Dr. John North, then living London, but later Master of Trinity College, Camidge. The present owner of the letter, Mr. Roger orth, of Rougham, King's Lynn, Norfolk, who has aced it in the custody of the Royal Society, makes e very probable suggestion that the "new Treatise Musick", with which the letter deals, was "A ilosophical Essay on Music", by Francis North, ord Guilford, to whose brother the letter is ldressed.

The letter is written on both sides of a sheet of per measuring about 15½ in. by 12 in., in a very at and easily legible hand, which is certainly that Newton. One half of one side was left blank, so at on folding for postage it could be addressed ithout envelope. On one of the blank oblongs left y this folding, the letter has been further identified y endorsements written by (1) Roger North, son the Hon. Roger North of Rougham and nephew Dr. John North, the recipient; and (2) Frederick orth, great-grandson of (1) and great-grandfather the present owner, Mr. Roger North of Rougham. he fine state of preservation is explained by the ct that, as Mr. North informs me, the letter had een kept continuously between the leaves of a folio olume in the family library, until he recently had framed between plates of glass.

The scientific world is indebted to Mr. North's enerous thought, which has now made the letter vailable for study by placing it in the Royal Society's ibrary. The publication of the following text of the locument will, meanwhile, make its substance available to the readers of *Nature*.

H. H. DALE.

Cambridge Apr 21.1677

Sr

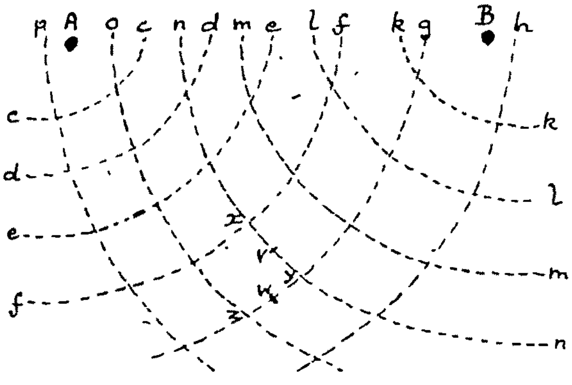
The esteem you express of my judgment I must impute to yo^r goodness who are willing to make y^e best of every thing. Yet since it is yo^r desire to have my opinion about this new Treatise of Musick, I shall give it you, though perhaps not so largely as you may expect, there being some things which I cannot speak positively to for want of experiments & skill in Musick.

Pag 5 lin 14 & pag 6 lin 30, the Author asserts y^t sound is produced in y^e Torricellian vacuum, & thence seems to collect y^t y^e medium of sound is not y^e grosser Air but some subtiler aerial fluid of a middle nature between y^t Air & AEther, wch can penetrate glass & other gross bodies. But it is to be suspected y^t this experim^t of y^e Torricellian Vacuū holds only when y^e glas is not well emptied of Air. For M^r Boyle (Exp^t 27) repeating it wth a watch hung in his Receiver, found that as y^e receiver was more & more emptied, y^e noise made by y^e Ballance wheel grew fainter & fainter till at last it was not heard at all though y^e handle & wheels of y^e watch were still seen to continue their motion as freely as at first. Yet y^e louder sound of a Bell continued audible when y^e air was drawn out, though perhaps it would not have done so could y^e Receiver have been fully exhausted of Air, & y^e Bell have been susteined in y^e Receiver by something w^{ch} might not touch y^e glas. To y^e best of my remembrance I have also some where read of an Alarm Watch whose Alarm being made to go, y^e sound of y^e Bell grew faint by drawing out y^e air.

Pag 5 lin 18 The Author asserts y^t a sound seems to come in streight lines to y^e ear though an obstacle be situated between y^e ear & y^e sounding body so y^t it cannot come in streight lines. But this I doubt of if, he mean y^t it seems to come in streight lines from y^e sounding body. If indeed y^e interposed obstacle be not too gross & compact, suppose a glass window or thin wall of wood or mortar, y^e air may by shaking it propagate y^e sound through it, & then y^e sound will be heard in a streight line from y^e sounding body: but if y^e obstacle be massy, suppose a very steep & high hill or a solid high wall of brick or stone, I am apt to think y^e sound will seem to come from y^e top of y^e Hill or Wall rather then in a direct line from y^e sounding body behind it. And some such diverting of sounds I have observed occasionally, in walking on a street close by a single House whilst bells were ringing on y^e other side. The house to y^e best of my remembrance had no windows on that side next me & y^e sound of y^e bells seemed to come from y^t end of y^e house w^{ch} I was nearest to, though y^e bells were directly behind it so in a Room of stone walls wth but one window, the sound will seem to come from y^e window though y^e sounding body without lye not that way.

Pag 8 lin 14 The Author affirms y^t where y^e vibrations of two sounding strings are equal, they will work one another to a coincidence or synchronism, & on this position grounds all his discours of concords & discords, affirming y^t unisons alway strike y^e ear together, Octaves at every other puls of y^e Treble, fifts at every 3^d pulse &c. But it seems otherwise to me for though y^e pulses of y^e strings should reduce one another to a synchronism, yet those of one string will strike y^e ear sooner or later then those of y^e other, accordingly as y^e ear is more or less near to one string then to y^e other.

Since sounds are not propagated in a moment, y^e pulses must not be supposed to extend each of them at once from y^e sounding body to y^e ear in such manner y^t all y^e air in that interval be moved together first forward & then backward, & so forward & backward again so long as y^e sound lasts: but y^e pulses are rather to be conceived like so many spherical concentrick waves whose center is y^e sounding body & w^{ch} arising continually from y^t center dilate & flow on from thence with that swiftness we find sound propagated till they arrive at y^e ear; new pulses from y^e center continually succeeding them after y^e manner of undulations made by throwing a stone into water. Let therefore A & B represent two sounding bodies of like tones, c,d,e,f, &c y^e pulses continually propagated from A; & k,l,m,n, &c y^e pulses propagated from B. And if y^e ear be placed at x, or y, or z, or any place where y^e pulses at any time intersect, they will strike y^e ear at y^e same time, but if it be placed between x, & y suppose at v, y^e puls xn w^{ch} comes from y^e Body B will strike it in y^e intervall of y^e pulses xf & yg w^{ch} come from y^e body A. And the like will happen if



y^e ear be placed between y & z as at w, or in any pulse of one body & between two pulses of y^e other. So that y^e ears of two men or y^e two ears of y^e same man according to their position from y^e sounding bodies may be struck the one at once y^e other successively by y^e pulses, & yet in all positions of y^e ear y^e sounds & their harmony are heard y^e same. The like of bodies tuned to a fift or any other Concord. Seing therefore y^e pulses of two sounds may at y^e same time strike one ear both together & another ear alternately & yet do exhibit y^e same concord to all ears, it follows 1st that concords arise not from y^e coincidence of pulses at y^e ear nor have any dependance on such coincidences, & 2^{dly} that unisons are rather a harmony of two like tones then a single tone made more loud and full by y^e addition as y^e author would have it, p.8.1.20.

The explication of y^e sound of whistles pag 12 is very ingenious, but I fear not altogether substantial. Yet for want of apposite experiments I can neither sufficiently confute it nor confirm any new Hypothesis.

The discours also about breaking of Tones into higher notes seems very ingenious & judicious, but I want experience to discern whether altogether solid, & much more do I want experience & skill to enable me sufficiently to judge of what follows about Tunes, y^e scale of Music, & consort; this requiring a combination of musical & mathematical skill, & therefore I shal content my self wth having thus far animadverted upon y^e Author.

I am much obliged to you for giving me notice of the objection made against my notion about colours. But y^e experiment succeeds otherwise then tis reported. If you place your eye where y^e blew light falls on y^e wall so y^t a by-stander see your eye of a blew colour you will at y^e same time see y^e Prism of a blew colour; and so if you place you eye in y^e red light you will see y^e Prism red. What colour a By-stander sees fall on yo^r eye you will see at y^e Prism: as I can affirm by iterated experience.

The last week I called at yo^r Lodgings & hope ere long to have an opportunity to wait on you again. In y^e meane time I rest wth my thanks to you for yo^r kind acceptance of my former Letters

Yo^r humble Servant
& honourer
Is. Newton

ENZYME ACTIVITY AS A FACTO IN INSECT PHYSIOLOGY AND TOXICOLOGY

By Dr. H. HURST
Department of Colloid Science, Cambridge

FOR many years the search for new insecticides ha proceeded on the working hypothesis tha toxicity is related to highly specific molecular configurations in the insecticide molecules. An excellen example of the analytical approach used by th chemist has been provided recently by Lauge Martin, and Müller, who have made an exhaustiv and critical examination of the constitution and toxi action of natural insecticides, such as pyrethrins an rotenone, and in particular, the new synthet insecticide D.D.T. (α,α-bis-(4-chlorphenyl)-β,β,β-tr chloroethane)[1]. But before any evaluation of insecticidal activity may be made in terms of specific grou concepts, it is necessary to take into account som less specific dynamic factors in activity. In thi connexion, the carrier medium in which an insecticid is dissolved may alter the permeability of the insec cuticle and so modify access of insecticide to th internal tissues[2].

The importance of this rate factor in access o insecticide becomes apparent if we make the vali assumption that insecticidal activity is associated with some disturbance in the chain of consecutiv vital processes which regulate the dynamic balanc in internal tissue metabolism. If gross biological responses, such as paralysis or death, can be identified more specifically with changes in enzyme activity, a step forward will have been taken towards the elucidation of the more interesting anomalous systems in insect toxicology where there is no apparent coincidence between molecular structure and insecticidal activity.

These concepts will be illustrated in the present article, where an attempt is made to define the biophysical factors which influence the uptake of insecticide by the insect cuticle and internal tissue receptors. Some new factors in insecticidal activity will be described, depending on the discovery that phenoloxidase activity in the cuticle and sensitive tissue receptors* may be greatly modified by the selective environmental influence of the structural components associated with the enzymes *in vivo*. Narcosis, or knock-down action, may involve the indirect blocking of enzyme activity by the adsorption of insecticide on the protective lipo-protein tissue components. Lethality usually involves an irreversible increase in phenoloxidase activity owing to the displacement of protective lipoid from the tissue receptor complex. This stage is accompanied by the accumulation of toxic quinonoid metabolites in the blood and tissues, and is characteristic of the lethal action of insecticides and simpler fat-soluble drugs. Relative susceptibility of insects to contact insecticides depends partly on cuticle permeability, but more fundamentally on the stability of the internal tissue receptors which regulate the internal balance in oxidative metabolism.

Apart from differences in molecular structure, insecticides as a class are fat-soluble. The access of contact insecticides involves the uptake and storage of insecticide by the outer lipophilic epicuticle layer of the insect cuticle. In blowfly larvæ, such as *Calliphora erythrocephala*, or *Phormia terrænovæ*, the soft cuticle is hydrophilic, and the receptor surface of the epicuticle is heterogeneous, consisting of a mosaic arrangement of lipoid and protein receptor patches[3]. Even where the cuticle is waxy, as in *Tenebrio molitor* larvæ, the presence of protein receptors in the epicuticle may be demonstrated by means of protein anning reagents. Pryor[1] has stressed the analogy between the natural tanning of insect cuticle and the tanning of gelatine by *p*-benzoquinone, but whereas the tanning of insect cuticle by *p*-benzoquinone takes place more rapidly in organic fat solvents than in aqueous substrates, this selective carrier activity is not shown with lipoid-free proteins such as gelatine. Fat solvents which increase the permeability of the cuticle to water-insoluble insecticides, such as pyrethrins or D.D.T., also increase the rate of access of *p*-benzoquinone, so that a given concentration of the reactant is more active in an oil than in an aqueous carrier medium[3].

---

* The term 'receptors' is frequently used in pharmacology to indicate the sites of action in biological systems with which drugs are supposed to combine or exert specific actions.

Here we have a clue to the nature of the spatial changes induced in the epicuticle receptors by the fat-solvent carriers, for these changes must increase the permeability of the cuticle both to fat-soluble and to water-soluble drugs. Similarly, the sensitization of the cuticle by fat solvents is associated with an increase in the permeability of the cuticle to water, suggesting a displacement of protective lipoid from the more hydrated receptors[2,5]. Morphologically, the epicuticle receptor system must be consistent with toxicological and physiological behaviour. The lamellar structure of insect cuticle suggests that the plane of orientation of the epicuticle lipo-protein micelles is parallel to the cuticle surface. This is further supported by the X-ray diffraction studies of Fraenkel and Rudall on the chitin-protein crystallites of the bulk cuticle framework[6]. Chargaff has shown that the association of a lipoid, such as cephalin, with basic proteins, such as histone or protamine, results in the formation of relatively stable lipo-protein complexes owing to the interaction of the negative groups of the cephalin with the positive groups of the protein[7]. This complex-formation is accompanied by the expulsion of water from the hydrated protein. Since the tanning of the cuticle by *p*-benzoquinone probably involves the interaction of the quinone monomer with the $-NH_2$ groups of the protein side-chains in the lamellar cuticle fabric, it is likely that fat-solvent sensitization of the epicuticle involves the spatial displacement of lipoid, possibly of the cephalin type, which is normally attached to the basic side-chains of the protein receptors

The physiological requirements of the cuticle as a membrane impermeable to water would be satisfied by the intercalation of labile lipoid between the protein-rich structural lamellæ of the epicuticle framework. But the association of a fat-solvent with such a simplified lamellar fabric would not induce rapid access of water-soluble or oil-soluble drugs, owing to the discontinuous nature of the lamellar receptors across the cuticle framework. However, a microscopic mosaic network of lipophilic and more hydrophilic receptor patches can be detected in the epicuticle of *Musca domestica* larvæ which have been artificially tanned with *p*-benzoquinone. The interaction of the monomer with the protein receptors is accompanied by its oxidation and polymerization *in situ*. In this way a further degree of rigidity and stability is conferred on the epicuticle framework and inner cuticle layers. The brown polymerized oxidation products of the quinone do not become uniformly distributed throughout the epicuticle, but form a mosaic of dark tanned patches enclosed within a more continuous refractile network. These discrete receptor loci are approximately 2–2·5 μ in width when seen in optical section and extend radially across the epicuticle framework to a depth of about 3 μ. When the cuticle is sensitized with a fat-solvent, the mosaic tanned network becomes more diffuse; but tanning takes place most rapidly in the discrete patches within the refractile network, showing that protective lipoid is selectively displaced from these receptor zones. After prolonged contact with fat-solvents, the labile lipoid becomes eluted from the epicuticle framework, and even the refractile regions are tanned rapidly by *p*-benzoquinone.

By combining such a mosaic receptor system with a lamellar epicuticle framework, the access of drugs becomes consistent with the physiological role of the epicuticle as a protective water-impermeable barrier, which conserves essential water in the living insect. The primary uptake of fat-solvent by the lipoid-rich mosaic receptor network increases the continuity and permeability of this phase across the epicuticle. At the same time, the immobilization and storage of fat-solvent within these loci dissolves or displaces the adjacent inter-lamellar lipoid, which accumulates in the transverse lipophilic network and increases the relative phase volume of this system. There is thus an increase in the continuity and permeability of both the lipoidal and protein-receptor components of the mosaic across the cuticle framework.

The natural hardening or tanning of insect cuticle is an enzymic process, and Dennell has provided interesting evidence to show that the localization of a phenoloxidase and polyphenol in the epicuticle of *Sarcophaga falculata* larvæ may partly explain the more rapid hardening of the outer cuticle layers[8]. According to Dennell, the polyphenol substrate of the cuticle is an oxidation product of tyrosine, which is oxidized in the blood by the enzyme tyrosinase and diffuses into the outer layers of the cuticle. The isolated cuticle of *Musca* larvæ and other insects darkens in the presence of tyrosine or catechol substrates, but hardening does not take place in the tyrosine substrate. On the other hand, a tanning process, which is analogous with the natural changes *in vivo*, occurs in catechol substrates; but the action differs from the tanning in *p*-benzoquinone substrates in that the reactive *o*-quinone is formed enzymically within the cuticle framework after access of catechol has taken place.

The natural tanning of insect cuticle, however, does not simply involve the combination of the natural polyphenol substrate with molecular oxygen in the presence of polyphenol oxidase. The addition of hydrogen peroxide to an aqueous catechol substrate greatly increases the rate of tanning of the cuticle even when the enzyme receptors have been exposed by fat-solvent sensitization. This reaction is thermolabile, and is due to the presence of a highly active polyphenol peroxidase which is secreted into the cuticle by specialized epidermal cells. Enzymic tanning may be accelerated by the presence of fat-solvents in the cuticle framework similarly to the induced tanning by *p*-benzoquinone, and this suggests that the labile protective lipoid is attached to the enzyme prosthetic groups. That the polyphenol peroxidase is associated with the protein structural components of the epicuticle mosaic is shown by the coincidence in the mosaic pattern which develops in

p-benzoquinone and in catechol substrates, but this pattern is still further intensified in the presence of hydrogen peroxide. The natural polyphenol substrate is secreted by epidermal cells into the epicuticle by means of a network of ducts which open by discrete pores on the surface of the epicuticle. The selective concentration of polyphenol in these zones produces local darkening of the cuticle in ammoniacal silver nitrate solution. The cuticle peroxidase is similar in many respects to the peroxidase in horseradish roots[9]. Catechol is rapidly oxidized by an aqueous horseradish root extract in the presence of hydrogen peroxide. The natural hardening of insect cuticle can be accelerated by abrading the outer cuticle surface and treating the abraded areas with a concentrated aqueous horseradish extract.

The cuticle peroxidase appears to play an important part in the determination of macroscopic cuticle pattern. In *Musca* larvæ and in related blowfly larvæ, the whole cuticle becomes uniformly tanned after sensitization with a fat-solvent and immersion in an aqueous substrate containing catechol and hydrogen peroxide. This is analogous to the formation of the puparium *in vivo*; but in other insects, such as *Tenebrio molitor* larvæ, a segmental cuticle pattern may be developed in a similar manner to the appearance of an image on a photographic plate by this treatment.

These examples of cuticle sensitization have been selected to show how the association of a simple fat-solvent with the cuticle receptors may initiate a complex chain of interdependent biological changes. The physical nature of the primary stimulus is shown by the fact that cuticle sensitization may be brought about by rubbing the cuticle with adsorbent powders, such as silica, charcoal, or alumina. These powders, which also act as 'inert' insecticidal dusts, not only increase the permeability of cuticle by local 'abrasion' of superficial epicuticular lipoid, as Wigglesworth has shown[10], but also induce a more uniform displacement of internal protective lipoid by adsorbing superficial lipoid from the outer layers which communicate with the internal mosaic receptor network[3]. The coincidence between the segmental tanned cuticle patterns which develop when *Tenebrio* larvæ are sensitized by fat-solvents and by the action of adsorbent powders indicates that both treatments expose the more internal peroxidase receptors to access by catechol.

In these systems there is a competition between the protective lipoid and the substrate catechol for the cuticle peroxidase receptors. But a still more complex competition is shown between two enzymes in the cuticle framework for the same component in the substrate. Peroxidase activity is inhibited by the enzyme catalase, which decomposes hydrogen peroxide into water and molecular oxygen, and so prevents the accumulation of toxic concentrations of hydrogen peroxide in the tissues. The outer epicuticle is permeable to peroxidase, but not to catalase, and the progressive hardening of the cuticle from the outside inwards which takes place *in vivo* and in catechol substrates containing hydrogen peroxide is due to the gradient of peroxidase inhibition produced by the selective localization of catalase within the cuticle framework. Similarly, selective access of catalase to the thinner intersegmental regions of the cuticle in *Tenebrio* larvæ inhibits peroxidase activity, and so the flexibility of the cuticle in these regions is maintained during the hardening of the cuticle. Here is a very interesting example of how physiological function in a protective membrane may be influenced by the selective competition of enzymes within the membrane fabric. This selective segmental tanning is not shown in p-benzoquinone substrates. In these systems, tanning of the cuticle depends on the general availability of protein receptors within the membrane, and tanning takes place at the intersegmental membranes.

If, by analogy with the cuticle receptor system, we assume that the toxicity of insecticides at the internal tissue receptors depends on the disturbance of the dynamic physiological balance in oxidative tissue metabolism, it becomes possible to obtain some insight into the way in which insecticides and simpler drugs of different molecular structure exert similar pharmacological actions. For example, the cuticle and tissue phenoloxidases are relatively diffusible*, and the relation between tissue peroxidase activity and the drug concentration of the hæmolymph may be studied by removing some of the cuticle from the body wall of mature *Musca domestica* larvæ and immersing the insects in standard volumes of phosphate buffer (pH 7·4) containing fixed concentrations of catechol (0·5 per cent) and hydrogen peroxide (5 per cent of 10 vol. solution), and variable concentrations of a simple narcotic, such as ethyl alcohol. The rate of enzymic oxidation of the catechol may be measured by the reddening of the tissues and substrate. Typical results show that with increase in the alcohol concentration of the substrate (0–6 per cent) there is a progressive decrease in peroxidase activity accompanied by the inception of narcosis in the insect. With further increase in alcohol concentration (6–25 per cent) there is no marked change in peroxidase activity; within this range drug tolerance is shown by the persistence of narcosis. This reduction in peroxidase activity cannot be due to direct combination of the alcohol with the enzyme, for with higher concentrations of alcohol (25–60 per cent), peroxidase activity rises to a maximum value higher than that in the control system in which alcohol is absent. With still further increase in alcohol concentration, peroxidase activity decreases owing to tissue denaturation. These selective changes in peroxidase activity are not shown by aqueous extracts of tissue where the enzyme is no longer associated with the structural tissue organization.

From this unusual relationship between the drug concentration in the substrate and tissue peroxidase activity, it may be inferred that the competition between a drug and a specific substrate for an enzyme does not necessarily take place according to the mass action law which generally holds in liquid non-structural systems containing isolated enzyme preparations. The selective environmental influence of a tissue component sensitive to a narcotic is shown by the parallelism between the changes in catechol peroxidase, catechol oxidase, and tyrosinase activity which takes place in the appropriate systems with change in the concentration of alcohol in the substrate†. Moreover, the rate of change of phenoloxidase activity with concentration of drug varies with different insects. For example, hæmolymph concentrations of ethyl alcohol, which decrease tissue phenoloxidase activity in *Musca* larvæ and induce narcosis, may increase phenoloxidase activity in *Tenebrio* larvæ. Within critical ranges this increase is lethal and results in the darkening of the blood owing to an increase in tyrosinase activity. Here the substrate is tyrosine, which is a product of tissue metabolism. The intermediary stages in the tyrosinase-tyrosine reaction have been elucidated by the classical work of Raper[11]. It is clear that, in addition to a factor of cuticle permeability, the relative susceptibility of insects to the same insecticide will depend more fundamentally on an internal environmental factor associated with the stability of the tissue receptors.

---

* This diffusion of enzymes, which are of high molecular weight, is brought about mainly by convection transport in the hæmolymph and by the movements of the living insect.

† The increase in catechol oxidase activity in the presence of lethal alcohol substrate concentrations may also be demonstrated using manometric methods, which show the correlation between the reddening of the substrate and the oxygen uptake. Similarly, colour formation and oxygen uptake are decreased by inhibitors such as hexyl resorcinol.

The components sensitive to a narcotic must be such that the affinity of monohydric alcohols for these structural receptors is greater than the affinity of the drugs for the phenoloxidase systems. The nature of these accessory receptors is shown when a comparison is made between the narcotic actions of the lower members of the homologous series of monohydric alcohols. In *Musca* larvæ, the exponential rate of decrease in the threshold concentrations of narcotic in the substrate or drug in the hæmolymph as the series is ascended from methyl to amyl alcohol forms a Traube series characteristic of drug distribution between immiscible oil/water phases. Similar results have been described for related blowfly larvæ[2]. From this evidence it would seem that the narcotic sensitive tissue receptors are lipoidal, or more probably lipo-protein in nature. The increase in phenoloxidase activity at lethal concentrations of drug suggests that the permeability of the tissue receptors to drug and essential substrate molecules is increased by the displacement of protective lipoid from the protein-enzyme tissue complex. But apart from this permeability factor, depending on lipoid solubility, the lipoid receptors also influence the steric approach of the drug to the enzyme receptors, for with the capillary-active alcohols reduction in tissue phenoloxidase activity takes place only within the range of biological drug concentrations where the displacement of protective lipoid is reversible. At higher lethal drug concentrations, this selective steric factor is no longer dominant owing to the dispersion of protective lipoid from the enzyme. In a similar way, access of substrate catechol is influenced by the non-polar association of the benzene nucleus of the catechol molecule with the lipoid receptors, and by the more specific two-point polar attachment of the hydroxyl groups of the catechol with the prosthetic groups of the enzyme.

One important result which emerges from these biological complexities is that narcosis and lethality are only indirectly related to changes in aerobic phenoloxidase activity, owing to the selective environmental influence of the tissue receptors sensitive to a narcotic. But it is known that the tissue or cell dehydrogenases are also inhibited by narcotics or depressants, and in order to gain an insight into the nature of drug specificity it is necessary to study the action of these drugs on the aerobic and on the anaerobic components of respiratory systems. Dehydrogenase activity is usually studied by determining the rate of reduction of an autoxidizable dye, such as methylene blue, in the presence of tissue, substrate, and drug, under anaerobic conditions. When methylene blue is injected into the hæmolymph of insects, the dye is taken up by the tissues, and is partly or completely reduced, depending on the concentration of dye present, and on the oxidation-reduction potential of the substrate. If drugs are now applied externally to the insect cuticle, the change in the colour of the dye, which may be observed through the cuticle, gives an indication of the relative changes in dehydrogenase activity. At the same time, the darkening of the blood and tissues provides a measure of the changes in aerobic tyrosinase activity. In this way the dynamic changes in aerobic and anaerobic oxidative processes may be compared under conditions in which insecticides are usually applied to insects *in vivo*. Suitable test insects are *Tenebrio molitor* larvæ, or mature *Musca domestica* larvæ. Some significant conclusions emerge when a comparison is made between the action of simple non-polar and polar or capillary-active drugs. These may be summarized briefly as follows.

(1) Both the aerobic and anaerobic enzymic oxidative processes are influenced by the tissue receptors sensitive to a narcotic.

(2) The transition from narcosis to death induced by the action of non-polar fat-solvents such as hexane, *cyclo*hexane, benzene, or chloroform is accompanied by an increase in tissue phenoloxidase activity and tissue dehydrogenase activity, suggesting a sensitization of the structural lipo-protein tissue receptors which is analogous to that induced in the mosaic lipo-protein receptor organization of the insect cuticle.

(3) Increase in the hæmolymph concentration of primary monohydric alcohols produces a similar sensitization of the tissues as non-polar fat-solvents, but with the lower members (methyl → propyl alcohol) the increase in tissue tyrosinase at lethal concentrations in the hæmolymph is accompanied by an inhibition in dehydrogenase activity, suggesting a more specific susceptibility of these systems to the alcohol hydroxyl group. The competition between the lipoid tissue receptors and the dehydrogenase receptors for the drugs is shown by the fact that, as the drug series is ascended from propyl to butyl alcohol, the inhibition of dehydrogenase activity falls off sharply, and with higher homologues the fat-solvent properties of the molecules are dominant factors in activity.

(4) With the related homologous series of monocarboxylic acids the relatively strong polar interaction of the carboxyl groups with the protein-enzyme receptor complex is dominant, and both phenoloxidase and dehydrogenase activity are inhibited by low concentrations of drug in the hæmolymph.

(5) The narcotic and lethal actions of non-polar fat-solvents and inert fat-soluble drugs, such as primary alcohols, are probably associated mainly with changes in aerobic oxidative enzyme activity. The phenoloxidase systems in *Tenebrio* larvæ are much more sensitive to drug-dispersant action than in *Musca* larvæ, where the insects are much more resistant to the narcotic action of fat-solvents in general. On the other hand, the tissue dehydrogenase systems show similar degrees of susceptibility in both species of insect.

These principles appear to be of general application in wider fields of pharmacology and suggest that the discrepancies which have hitherto existed between the simple principles of Overton-Meyer, Traube and the somewhat static specific group concepts of Ehrlich are fundamentally biological. The changes in enzyme activity, which are dependent on changes in the selective environmental influence of the lipo-protein tissue receptors, suggest the interesting possibility that the cytochrome system, which is probably the most important component of the respiratory system in insects and other organisms[12], is similarly influenced, and it is hoped to investigate this aspect by the use of spectroscopic techniques.

When we come to examine more complex insecticidal systems, it is clear that similarity in biological response may merely indicate a coincidence in the dynamic chain of metabolic changes initiated at different links in the chain. For example, pyrethrins I and II are complex unsaturated ketonic esters which differ completely in molecular structure from the relatively simple inert fat-soluble D.D.T.[1]. Yet similarity in insecticidal action is shown by a dispersant action on the cuticle and internal tissue lipoids, and the lethal stages of poisoning reveal an increase in the phenoloxidase activity of tissue and hæmolymph. The minute nature of the lethal dosages is consistent with an adsorption process on the tissue receptors; but it is unlikely that narcosis or death is directly related to primary insecticide-tissue combination. A contributory factor may be the accumulation of reactive *o*-quinones which would block essential substrate access to the whole complex of enzyme systems normally associated with the tissue components. This narcotic stage would be followed by death when the further dispersant action of the insecticides resulted in the accumulation of lethal concentrations of toxic quinonoid metabolites in the tissues. Richter[13] has shown the general similarity between the catechol oxidazes in plants, fungi and insects, and has found that oxygen uptake is greatly reduced by the *o*-quinone reaction products, which combine with the available catechol oxidase. However, these more specific factors in insecticidal action are beyond the scope of the present article and will be considered elsewhere.

This account is based on an investigation into the fundamental mode of action of insecticides and drugs which is being carried out by me at the Department of Colloid Science, Cambridge. I wish to express my deep indebtedness to Prof. E. K. Rideal and to Dr. J. H. Schulman for much helpful advice and stimulating discussion, especially on the physico-chemical aspects of the work.

OBITUARIES

Miss E. R. Saunders

WHEN Edith Rebecca Saunders died on June 6 at the age of eighty as the result of a bicycling accident in Cambridge, there passed one to whom many scientific women owe a great debt for her labours on their behalf in the early days of the higher education of women. Others have written of the value of her botanical research work, but not the least valuable part of her services was the organization and training of many generations of science students at Girton and Newnham Colleges.

In the early days of the higher education of women at Cambridge, the University lectures were not open to women and the teaching of science was left entirely to the women's colleges to provide as best they might. Friends of the women helped when they could, but there was no help from the University as such. Very soon after Miss Saunders had taken her Tripos she was appointed demonstrator in biology at Newnham College and taught the students of both Girton and Newnham Colleges; later she became a lecturer, and together with the late Mrs. Bidder (Marion Greenwood) helped to organize all the practical work in biology and botany given in what came to be known as the Balfour Laboratory. This building, a former Nonconformist chapel given to Newnham College by the generosity of Mrs. Sidgwick and Miss Balfour in memory of their brother Francis Maitland Balfour, the zoologist, was converted into the Balfour Laboratory under the direction of Miss Greenwood and Miss Saunders, and here Miss Saunders taught for many years, becoming its director after Miss Greenwood's marriage to Dr. Bidder.

She always set before her pupils a high standard, and much excellent work was carried out by them there. Even after many University professors and lecturers opened their lectures to women, all the practical work for Part I of the Tripos was still organized and carried out by her, until the new University Laboratories were built and accommodation provided in them for the women students.

There must be many women employed in scientific work in universities, colleges, schools and other places all over the world who know that they owe their present position and success largely to the stimulus of Miss Saunders' teaching and the high quality of the work on which she insisted.

G. L. ELLES.
ETHEL SHAKESPEAR.

THE main writings of Miss E. R. Saunders relate to floral morphology. The most important of them were issued between 1923 and 1936 in the *Annals of Botany*, the *New Phytologist*, the *Journal and the Proceedings of the Linnean Society*, the *Journal of Botany* and the *Journal of Genetics*, and in two volumes published by Messrs. Heffer and Sons. The earliest of them furnished a factual basis for a new and interesting outlook on gynœcial morphology; the later documents elaborated a theory of carpel polymorphism and brought to focus important problems of systematic and evolutionary interest which are still unsolved.

The first of these writings appeared at a time when some rendering of the classical conception of a monomorphic carpellary 'leaf' gave contentment to many inquirers. They looked on such an organ as the basic unit of gynœcial construction in all groups of flowering plants and thought of it as possessed of a median style and a distal stigma. Whatever was their mode of approach to floral matters, their common purpose was to settle long-standing differences of opinion regarding the 'basic numbers', arrangements and forms of such 'leaves' for all types of 'syncarpous' gynœcia and to furnish for each alliance a 'fundamental ground-plan of floral construction'.

Few indeed were prepared to describe precisely the 'foliar' prototypes of which they spoke; but many acted on the view that such common 'free' carpels as follicles and achenes exemplified their units and demonstrated some of the ways in which still older organs had been transformed, reduced in numbers, aborted or suppressed, and gradually rearranged on some uniform specific plan. Despite their union in pistils, they still showed, per species, a single carpel-form. Nevertheless, although there was constant reference to facts of development and histology and to all manner of final forms of pistil, opinion on gynœcial construction had come no nearer to harmony than it had been from the days of Braun and Eichler to those of Kerner and Klein.

The bearing of Miss Saunders' views may be made plain through a few points of past interest. Thus, while some believed that facts of development were of great value in the interpretation of all organs, others considered that adult form and structure gave the surest guide. There was also a mode of thought which gave prominence to vascular tissue not only as a major index to the status of an organ but also as a sign of its modification, or as a pointer to its prior development in a given position. There was a common language explaining the arrangement of vascular strands, their modes of branching, the remarkable conservatism of a vascular system, and the usefulness of 'vestigial' strands in tracing the old sites of arrested organs. Further, some believed that a leaf may be truly terminal since, as they said, a legume is a unit carpellary leaf and is fully distal. Others rejected this view and regarded a legume as the sole and displaced survival of a lateral group of 'leaves'. They read all 'syncarpous' gynœcia according to their notions of numbers and arrangements of lateral leaves, of those which had been suppressed, and of those which were now displaced.

Miss Saunders entered this field convinced that there could be no agreement on a 'fundamental ground-plan' for any pistillate family so long as the concept of a monomorphic carpel was the starting point in phyletic discussion. She pointed, in particular, to the unsettled controversies over pistil construction in the Cruciferæ and other affinities, to the seemingly insoluble problem of the 'commissural' stigma, to the varying interpretations of obdiplostemony, to the wide range of ovule placentation still unexplained, and to the difficulties facing all monomorphists when they turned to families with 'supernumerary' styles. For these and all related matters she claimed the need of a new approach.

Her first proposal was as startling as it was simple, in that it visualized carpel dimorphism as shown to-day by many flowering groups. The heart of her view was that even a single pistil comprises united leaves; some with the form and the function of ovule-bearing organs, others of distinctive form and the function of which is stigmatic. Through this she sought early to rationalize cruciferous and other gynœcia and to explain the presence of commissural stigmas. As did others who opposed her plan for an extension of a 'leafy' view of carpels, she relied largely on the form and vasculation of mature organs. She came to identify and arrange her united carpel forms according to her estimate of branched or unbranched vascular strands, the positions of ovules upon ovarial walls, the arrangement of stigmas, and the older conception of the cyclic construction of a flower. It was inevitable that she should reject the conception of a terminal leaf once she had decided to interpret a distal legume as a union-product of distinctive carpel forms. Also it was natural that, with strands as a major instrument in the identification of unit organs, she extended her dimorphic view into a doctrine of carpel polymorphism. One cannot attempt to outline the many directions in which she sought later to apply her theory and to settle once and for all the fundamental ground-plans of floral construction on which she had set her heart. But her final volumes are in themselves a glowing testimony to the breadth of her inquiries, to her courage, and to the great array of facts which she disclosed.

It may be long before there is common agreement as to the chief objective of floral study and the valuation of the evidence on which Miss Saunders relied. But it may truly be said that few of her contemporaries in formal morphology stirred imagination more deeply than she, or did so much to stimulate inquiry. J. McL. Thompson.

Mr. H. E. Potts

The very narrow but nevertheless important field of patent law and practice has lost a great mind by the death of Mr. H. E. Potts on July 4. He was an earnest and original contributor to the literature of patent law. Early in his career as a chartered patent agent, he was struck by the fact that, in the drafting of patent specifications and claims, a patent agent had to call upon powers of analysis and then subsequent synthesis, and that this logical process should have some analogy in mathematics. His first contribution on "An Application of Mathematics to Law" was indeed to *Nature* of April 24, 1913 (p. 187), and this has been followed over the years by a development of the idea there lightly touched upon.

Although possibly never hitherto positively appreciated, it is nevertheless a fact that a patent granted upon an invention when tested by the High Courts of Great Britain is either 'wholly bad' or 'wholly good'. It is believed that Mr. Potts was the first to point out that there should be some method of assessing validity quantitatively, as well as qualitatively; and recently he put forward a number of suggestions in regard to the appreciation of monopolies of invention as granted by the Crown on a graduated basis, as distinct from the 'all good' or 'all bad', developing this proposition side by side with its mathematical exposition and following accepted theories of modern philosophy.

Of many valuable publications, perhaps Potts' best known is his book "Patents and Chemical Research", which has become a standard work in the literature on patents.

We regret to announce the following deaths:

Mr. A. D. E. Elmer, the distinguished plant collector and author of many papers on the botany of the Philippines, in July 1942.

Dr. Frank Blair Hanson, associate director for the natural sciences at the Rockefeller Foundation, formerly professor of zoology at Washington University, St. Louis, on July 21, aged fifty-nine.

Dr. Gustave M. Meyer, associate in biochemistry during 1913–41 at the Rockefeller Institute for Medical Research, known for his work on carbohydrates and tissue chemistry, on May 9, aged sixty-nine years.

The Ven. Lonsdale Ragg, founder and editor of the *Tree Lover*, and known for his drawings of trees, on July 31, aged seventy-eight.

NEWS and VIEWS

New Linacre Professor at Oxford : Prof. A. C. Hardy, F.R.S.

PROF. A. C. HARDY, whose recent appointment as Linacre professor of zoology and comparative anatomy at Oxford has been announced, is especially distinguished for his work in the sphere of oceanography. He is a leading authority on marine plankton, and throughout his researches has stressed the ecological aspect. Prof. Hardy started his career as a member of the Ministry of Agriculture and Fisheries Research Staff at Lowestoft in 1921, working on the natural history of the herring in relation to the plankton. In 1924 he joined the research staff of the *Discovery* as chief zoologist under the late Dr. Stanley Kemp. He went on the Antarctic voyage of 1925–27, and published, with the late Dr. E. R. Gunther, important results on the ecology of plankton animals in southern waters. These included studies of animal and plant interrelations (developing his hypothesis of animal exclusion), 'patchiness' of plankton, correlations of whale and plankton distribution, vertical migration and the combined effect of this with varying current systems at different depths.

In 1928 Prof. Hardy became the first professor of zoology and oceanography at the University College of Hull, where he developed on a large scale the use of his continuous plankton recorder, which he had originated while with the *Discovery*. He also demonstrated herring-plankton distribution correlations with his smaller plankton indicator, which has now become a commercial instrument. In 1942, Prof. Hardy was appointed regius professor of natural history in the University of Aberdeen. In recent years he has widened his interests to include the air, undertaking research on the aerial plankton, for which he has devised gear for catching insects in the upper air from kites and aircraft. Prof. Hardy is thus well fitted to help and enlarge the scope of the well-known ecological researches already being carried out at Oxford.

British Cotton Industry Research Association Fellowships

THE Council of the British Cotton Industry Research Association has decided to make an annual award of a limited number of research fellowships with the object of training young men in research methods in pure science, and particularly those branches of prime interest to the Association. The Association conducts research into the utilization of cotton, rayon, silk and synthetic fibres, and examples of scientific fields of present interest to the Association are: carbohydrate and protein chemistry; fundamental studies of high polymers; photochemistry; fundamental physical studies relating to properties of matter or electronics; theory of instrumentation; mathematics; studies on the colloidal state. The fellowships will be open to graduates of British nationality and will be tenable at any British university. Their value will depend on circumstances, but will not in any case be less than £200 per annum. The Association will be guided in its choice of the location of fellows chiefly by the type of research conducted by the professor under whose direction the candidate elects to work. Application for election to a fellowship should therefore be made through the professor and should be accompanied by a statement of the problem to be studied. It will be normal for the Association to wish to interview candidates, but the recommendation of the professor will be an essential and will carry great weight in the selection. Applications should be forwarded to the Director, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester, not later than two months before the commencement of the work.

The object of the fellowships being to train young graduates in fundamental research methods, they will not be awarded for specific problems in connexion with industry. Further, the results of researches carried out with the assistance of a fellowship will be published from time to time in the scientific journals at the discretion of the professor directing the work, and if deemed by him worthy of such action. The only condition attaching to publication will be that suitable acknowledgment shall be made by authors of the receipt of a fellowship. Without in any way implying direction of or interference with the research, the Association would wish to feel free through its director of research to discuss progress with fellowship holders from time to time, and fellows would be given opportunities to visit the Association's laboratories, and thus become acquainted with the problems of the textile industries. Save in exceptional circumstances, the Association will not make more than two consecutive annual grants to the same person.

College of Aeronautics

THE following have been appointed to be the Board of Governors of the College of Aeronautics for postgraduate instruction in aeronautical science and engineering, which, as announced in the House of Commons in October last, is being created in accordance with the recommendations of the Committee presided over by Sir Roy Fedden, the report of which was issued last year: Air Chief Marshal Sir Edgar Ludlow-Hewitt (*chairman*), Dr. W. Abbott, Mr. H. Burroughes, Sir Roy Fedden, Mr. J. Ferguson, Sir Harold Hartley, Sir William Hildred, Sir Melvill Jones, Dr. E. B. Moullin, Mr. J. D. North, Sir Frederick Handley Page, Mr. E. F. Relf, Dr. H. Roxbee-Cox, The Lord Selkirk, Air Marshal Sir Ralph Sorley, Sir William Stanier, Rear-Admiral T. H. Troubridge and Mr. W. E. F. Ward. Invitations are being extended to the Governments of the Dominions and India which may wish to be associated with the College to appoint representatives on the Board of Governors. Preliminary steps are now being taken with the view of opening the College some time in the course of next year in temporary accommodation to be provided at Cranfield, pending the provision later of permanent premises.

Sensory Devices for the Blind Committee

THE Council of St. Dunstan's has set up a committee to be known as the Sensory Devices for the Blind Committee, and the following have agreed to serve: Prof. E. D. Adrian, professor of physiology, University of Cambridge (*chairman*); Dr. Clifford Paterson, director of the Research Laboratories, General Electric Co., Ltd., Wembley; Mr. Thomas Smith, superintendent of the Light Department, National Physical Laboratory; Flight-Lieut. E. Barton; Dr. B. H. C. Matthews, head of the R.A.F. Physiology Laboratory, Royal Aircraft Establishment, Farnborough; Mr. H. L. Kirke, head of the Engineering Research Department, B.B.C.; and Sir Ian Fraser. The Committee has had two preliminary tings and on its advice St. Dunstan's has decided et up a Research Unit and to seek the full-time ices of a research physicist and a biologist. ough the generosity of an anonymous benefactor, bstantial sum of money has been made available the work of the Committee over a period of five rs. The Committee will not only investigate ling devices for the blind but also methods where- the printed word in an ordinary book can 'read d' to the blind; the improvement of recorded ing books; braille machines, and other apparatus. research work will include the better use of the e glimmer of sight which remains with many ple who are technically blind, and the sub- ation of the sense of sight by the other senses.

alization in the Visual Cortex

R. Gordon Holmes, in his Ferrier Lecture before Royal Society on "The Organisation of the Visual tex in Man" (*Proc. Roy. Soc.*, B, 132, 348; 1945), lt chiefly with the question of localization within visual area of the cerebral cortex. As he himself shown, by study of the visual-field defects result- from gunshot wounds of the cortex, there is arently a very sharp point-to-point representa- of the retina in the cortex. The conception of nite fixed anatomical connexions between each at of the retina and the corresponding point in cortex has been supported by recent histological lies of the actual nerve fibre connexions, particu- y by Le Gros Clark. Such a rigid fixed relationship ween retina and cortex would appear, however, stand in marked contrast to the situation in other ts of the cortex, notably the motor area, where alization is by no means sharp and undergoes con- erable physiological variations. But more recent ical studies have shown that there must be a d deal of plasticity in the functional organization the visual cortex. For example, patients suffering m hemianopia compensate for the loss of half the ual field by developing a new fixation point ('false cula') in the centre of the surviving field of vision; imilar adaptation occurs in a squinting eye. In h cases there must be a complete functional rganization in the cortex, though the fibre con- xions, of course, cannot change. The conclusion that, although there is an accurate point-to-point resentation of the retina in the cortex, the func- nal organization of the visual cortex is not thereby idly fixed; on the contrary, it exhibits consider- e plasticity.

cent Earthquakes

During April and the early part of May 1945, the ited States Coast and Geodetic Survey, in co- eration with Science Service and the Jesuit ismological Association, determined the provisional icentres of five earthquakes. The first two occurred April 15, the first at 2h. 35·2m. G.M.T. and the ond at 19h. 50·6m. G.M.T. The former had an centre at lat. 56° N., long. 164° E., which is east Kamchatka, and the latter an epicentre at lat. ·5° N., long. 108·0° W., which is off Mazatlan, xico. The third earthquake was on April 19 at h. 03·5m. G.M.T. from an epicentre near lat. 40° S., ng. 179° E., which is east of New Zealand. The rthquake of April 21 at 17h. 14·5m. G.M.T., accord- g to the calculations based on reports from twelve rthquake observatories (instrumental), had its epi- ntre at lat. 19·3° N., long. 100·6° W. Its depth of cus was below normal, probably 50–100 km. below the surface of the earth. The earthquake was felt in Mexico. The fifth earthquake was on May 19 at 7h. 55·8m. G.M.T. The provisional epicentre, based on instrumental reports from eight observatories, has been estimated at lat. 16·0° N., long. 98·4° W., which is west of Mexico.

Mr. E. W. Pollard, at his observatory at Binstead, Isle of Wight, registered five earthquakes during April, the first on April 15 being the greatest. May is reported as being a very quiet month, only two earthquakes being recorded, on May 9 and 19. The former was small and the latter medium strength.

Localization of Faults in Low-Voltage Cables

Practical limitations of well-known fault-locating tests are considered, and some new tests capable of high accuracy are described, in a paper read by J. H. Savage recently before the Institution of Electrical Engineers in London. The new tests include a D.C. valve-voltmeter circuit for core-to-sheath insulation faults, audio-frequency search methods for open circuits and radio-frequency tests for conductor defects. Mention is also made of fault localization based on wave-reflexion effects. The paper deals mainly with factory technique for rubber- and plastic-insulated cables; but some of the methods can be applied to other types and to field work. As faults on cables carrying current are accompanied by local changes of electric and magnetic fields, and circuit unbalance and wave reflexions can be produced, future developments are likely to be in the direction of electronic devices, because these are eminently suitable for detecting and recording such effects.

Chinese Visitors to Britain

Eight Chinese visitors of widely varying professions are visiting Britain as guests of the British Council: Dr. Wang Ging-Hsi, director of the Institute of Psychology of the Academia Sinica, a well-known Chinese physiologist; Dr. Sah Pen-Tung, president of the National University of Amoy, Fukien, who is a physicist especially interested in radio-engineering; Dr. Yang Chen-sheng, professor of Chinese literature, and acting dean of the College of Arts of the National University of Peking; Prof. Tung Li Yuan, librarian of the National Library, Peking; Colonel (Mrs.) Chow Mei-You, head of the Nursing School in the Army Medical School; Miss Gao Ren-Ying, acting national general secretary of the Chinese Y.W.C.A., who is studying social conditions in Britain; Miss Priscilla Huang and Miss Chi-yi Chen, both of whom are interested in children's and women's welfare and all services of rehabilitation of war casualties.

Canadian Awards for Postgraduate Training

The National Research Council of Canada is providing opportunities for postgraduate training in science for men and women whose studies have been delayed or interrupted by war service, either military or civilian. Three classes of award are available for the academic year 1945–46 as follows: bursaries (450 dollars) for students who have graduated with high distinction in scientific subjects; studentships (750 dollars) for students who have had experience in research work in science for at least one year following graduation; fellowships (900 dollars) for students who have given distinct evidence of capacity to conduct independent research in science. One group of applications is under consideration and awards will be announced before October 1, 1945. Additional applications received by November 15, 1945, will be considered and awards announced by December 31, 1945. Detailed information with respect to these awards and a copy of the required application form may be secured upon written application to the Secretary-Treasurer, National Research Council, Ottawa.

University of Durham: Appointments

DR. A. C. OFFORD has been appointed to the chair of mathematics in the Newcastle Division of the University of Durham. Dr. Offord was born in 1906, and was educated at University College, London, and at St. John's College, Cambridge, where he was elected to a fellowship. He has also been a lecturer at the University College of North Wales, Bangor. He joined the Mathematics Department at King's College, Newcastle-upon-Tyne, in 1941. His published work includes papers on the theory of divergent series, Fourier transforms, trigonometric intervals and the application of methods of the theory of probability to algebraic equations; he has also done work on integral functions.

Mr. W. H. F. Barnes has been appointed to the chair of philosophy in the Durham Division of the University of Durham. Mr. Barnes is thirty-six years of age. He was educated at Corpus Christi College, Oxford, where he was awarded the Haigh Scholarship in classics and the John Locke Scholarship in mental philosophy. He also held for two years a Senior Demyship at Magdalen College. Since 1936 he has been assistant lecturer and then lecturer in philosophy at the University of Liverpool. During 1941–42 he was in the R.A.F. and thereafter took a post as administrative officer in the Ministry of Supply. His published works include papers in periodicals on values, meaning and verifiability, action, Berkeley and Locke, and Richard Price.

University of London: Appointments

THE following appointments have been made in the University of London: Mr. Raymond Irwin, county librarian of Lancashire, to be director of the School of Librarianship at University College; Dr. John Yudkin, recently supervisor in biochemistry and physiology at Christ's College and Emmanuel College, Cambridge, to the University chair of physiology tenable at King's College of Household and Social Science; Dr. L. Dudley Stamp, since 1926 Sir Ernest Cassel reader in economic geography at the London School of Economics and Political Science, to the chair of geography at the School.

Announcements

DR. H. J. GOUGH, who has just been released by the Ministry of Supply (*Nature*, Aug. 11, p. 168), is joining Lever Brothers and Unilever Ltd. as engineer-in-chief, and will shortly take up his duties at Unilever House.

THE Nuffield Foundation has made a grant of £1,045 a year for five years for the stipend and pension contributions of a special research fellowship for Dr. E. Orowan to enable him to continue his work in the Cavendish Laboratory, Cambridge, on the plastic properties of metals; in addition, the Foundation will provide £455 a year for the same period towards the cost of the fundamental research work undertaken by him.

THE next three graduate memberships of the R Institution, open to recent graduates, of either of any university in the British Empire who l taken a degree with either first or second c honours in any scientific subject, will shortly awarded by the managers of the Institution. T memberships give the holder the privileges of att ing all lectures delivered in the Institution and use of the Library. Application forms can be obta from the General Secretary, Royal Institution Albemarle Street, London, W.1.

THE Gas Light and Coke Company has decide broaden the basis of its research programme an arrange for improved co-ordination of effort wi the Company. Dr. H. Hollings, hitherto the c gas chemist of the Company, has been appoi controller of research, and he now becomes respons for the activities of Watson House as well as t of the Fulham Research Laboratory. The follov further appointments have also been made: Mr. Dieterichs to be manager, Watson House; Mr. G Holliday to be manager, Gas Light Centre; R. H. Griffith to be senior research chemist; S. Pexton to be senior chemical engineer.

AT the annual meeting of the Genetical Soci the following officers were elected: *President*, C. D. Darlington; *Vice-Presidents*, Prof. R. Fisher, Mr. M. B. Crane and Dr. J. Hammo *Acting Treasurer*, Dr. D. G. Catcheside; *Secreta* Mr. W. J. C. Lawrence, John Innes Horticult Institution, Mostyn Road, Merton, London, S.W. and Mr. R. R. Race, Galton Laboratory Serum U at the Department of Pathology, University Cambridge.

MR. J. E. C. BAILEY, chairman and manag director of Baird and Tatlock (London), Ltd., been elected president of the Scientific Instrum Manufacturers' Association of Great Britain succession to Mr. Frank Wakeham, who retires a three years of office. Mr. Bailey is a member of Admiralty Chemical Advisory Panel, of the Co mission on Scientific and Laboratory Equipment the Conference of Allied Ministers of Education, of several committees of the British Standa Institution. Other officers of the Association a *New Vice-Presidents:* Mr. J. Hasselkus (Ross, Lt Mr. Frank Wakeham (Cambridge Instrument Ltd.), Mr. T. J. Offer (Chas. Baker); *Hon. Treasur* Mr. S. Borthwick (R. and J. Beck, Ltd.); *H* *Secretary:* Mr. G. A. Whipple (E. R. Watts and S Ltd.); *Members of Council:* Mr. H. A. Ca (J. H. Dallmeyer, Ltd.), Mr. G. A. Heed (A. Kersl and Sons, Ltd.), Mr. A. J. Hughes (Henry Hughes Son, Ltd.), Mr. J. Loxham (The Sigma Instrum Co., Ltd.), Major G. McAlpine (Kelvin, Botto and Baird, Ltd.), Mr. E. C. Sherren (Un Kingdom Optical Co., Ltd.); Mr. M. H. Ta (Taylor, Taylor and Hobson, Ltd.), Mr. H. A. Trepte (W. and J. George and Becker, Ltd.), W. N. Wheat (Chance Bros., Ltd.), Mr. H. H. Z (G. H. Zeal, Ltd.).

ERRATUM.—In the communication "Abnor Lignification in the Wood of some Apple Trees", Dr. A. Beryl Beakbane and Dr. Eleanor C. Thomps in *Nature* of August 4, p. 145, Fig. 1 has been invert that is, the section of the 'rubbery' branch is t marked (*a*).

Penicillin in Leishmania Infections

HE action of penicillin on leishmania infections not so far been reported in the literature. This deals with the treatment of four hamsters in- ed with an Indian strain of the parasite which previously been employed by me in chemo- apeutic tests[1]. The methods used were the same hose already described. The Golden Hamster *cetus auratus*) is the most suitable animal for erimental studies of this infection, since in their the disease, so far as is known, never shows ntaneous regression and finally causes death. The *itro* action of penicillin on tissue forms of the asite and on flagellate forms in young and old ures is also described. Thanks are due to the icillin Clinical Trials Committee of the Medical earch Council for a supply of material.

he animals weighed 60–80 gm. Two were treated the calcium salt of penicillin in saline three es daily over a period of eight days with doses 00 Oxford units at 3–4 hour intervals, partly by intraperitoneal and partly by the subcutaneous te. Two others received half this amount in the e way, the total dose for each of the two pairs g 9,600 and 4,800 Oxford units respectively, ch corresponds to 6–3 million units for a man of mal weight. The drug was tolerated without any oward symptoms. The spleen infections before atment varied from 5 to 200 Leishman-Donovan lies per field, as seen under oil immersion with × 10 eyepiece, and when smears were examined days after the end of treatment it was found that infections had progressed in the same way as se in two control animals. The drug had there- e exercised no influence on the course of the in- tion and parasitic cell division had taken place rmally. In the case of bacteria, Bigger[2] has gested that penicillin affects only dividing cells. rrod[3], from his experiments, considers that the idence on this point is conflicting. It is, wever, not certain that the drug can penetrate splenic cells which normally contain these tissue rms.

In four *in vitro* experiments, infected splenic tissue m hamsters was cultured for six to seven days media at 25° C. which contained penicillin in rious dilutions. A suitable number of control bes were used at the same time. The results are corded in Table 1. Accurate counts of flagell- es could not readily be made since they tend become agglutinated in masses under these nditions.

From Table 1 it will be seen that development of gellates took place in all the culture tubes in which e concentration of penicillin was less than 50 units er c.c , and growth proceeded as in the controls. At at concentration flagellates failed to develop in me tubes and the percentage of failures increased ith higher concentrations of drug. It should be oted that the upper concentrations are greater than hose likely to be obtained in the blood in clinical ractice. After seven days incubation it was found y the agar-cup method that in the highest con- entrations about 50 per cent of the penicillin originally present had disappeared. According to Bigger, the maximum effect of penicillin is exerted near body temperature, but culture of leishmania at 37° C. has not so far been found possible. The results suggest that the drug in the highest concentrations used had exerted some action on the parasite, but our penicillin sample contained only 150 Oxford units per mgm. and the impurities present may have influenced the results.

TABLE 1. HAMSTER SPLEEN INFECTED WITH *L. donovani* CULTURED IN PRESENCE OF PENICILLIN.

Units of penicillin per c.c. of medium	No. of experiment				Totals
	1	2	3	4	
400				5−	5−
200			5−	2+ · 2−	2+ . 7−
50	2+ . 2−	1+ : 4−	5+	7+	15+ : 6−
12·5	3+	6+	6+	7+	19+
3·2		6+	6+		12+
0·8		4+	6+		10+
0 2		5+	6+		11+
Controls	3+	6+	4+	5+	18+
No. of parasites per field in each hamster spleen cultured	1	300	200	40	

+ = active flagellates present.
− = flagellates absent.

Some further experiments were made with flagellate cultures of different ages. Inocula of equal size of young flagellate cultures were sown in media containing penicillin at similar concentrations to the above, as well as in control tubes. After incubation at 25° C. for six to seven days, the contents of the tubes were examined and rough counts made of the number of flagellates present. It was found that the flagellates in tubes containing penicillin were as active as, and their numbers differed but little from, those in the control tubes. These results are summarized in Table 2.

TABLE 2. ACTION OF PENICILLIN ON FLAGELLATE FORMS OF *L. donovani* IN CULTURE MEDIUM.

Units of penicillin per c.c. culture medium	400	200	50	12 5	3·2	Controls
Total no. of tubes used for each conc. of drug	8+ : 1−	13+ : 1−	13+	13+	4+	10+

+ = active flagellates present.
− = flagellates absent.

It will be seen from Table 2 that only in two tubes containing penicillin did flagellates fail to survive six days. We consider that the drug had no action on these forms even at the high concentrations used.

In a final experiment penicillin, in the same medium, was added to six-day old cultures of flagellates to give a concentration of 400 Oxford units per c.c. Four tubes maintained at 25° C. for four days showed no diminution in numbers or activity compared with controls.

[3] Garrod, L. P., *Brit. Med. J.*, 107 (Jan. 27, 1945).

A Thermostabile, Fungistatic Factor from *Escherichia coli*

WHEN cultivating *Penicillium notatum* Westl. and related fungi for the purpose of producing penicillin, it was soon noticed that the production of penicillin was inhibited by certain bacteria. It was proved that this was due to the fact that the bacteria in question formed an apparently enzymatic substance able to destroy penicillin. This substance, which was called penicillinase, was first demonstrated by Abraham and Chain[1] in *Esch. coli* and *M. lysodeikticus*. It was later found in paracolon bacilli[2], in *B. subtilis*[3,4], in penicillin-resistant staphylococci[5], as well as in various other micro-organisms[6,7,8]. In addition, commercial preparations of taka-diastase and clarase were found to have a similar effect[9,10]. Preparations of penicillinase, like those of other enzymes, are more or less thermolabile. The penicillinase from *Esch. coli*, for example, is easily destroyed by heat[1], whereas that from *B. subtilis*, on the other hand, seems to be more stable[3].

Occasionally the production of penicillin was found to be partly or completely inhibited from other causes which could not be determined.

An interesting observation in this connexion was made here about two years ago in experiments with the cultivation of *Penicillium notatum*. In some cases, in which the nutrient medium was not sterilized immediately after its preparation, but was allowed to remain a short time at room temperature before autoclaving, the rate of growth of the fungus decreased, with the result that the production of penicillin also decreased. (Disturbances in the production of pigment by the fungus were also noted.) Evidently some species of the micro-organisms which had developed before the medium was autoclaved had produced a thermostabile substance with fungistatic activity.

In later experiments to determine the ability of a number of bacteria to produce a substance of this kind, it was found that a strain of *Esch. coli* possessed this ability to a marked degree, particularly when the following medium was used: asparagine 2 gm., $NaNO_3$ 3 gm., KH_2PO_4 6·5 gm., $Na_2HPO_4,12H_2O$ 33·5 gm., KCl 0·5 gm., $MgSO_4,7H_2O$ 0·5 gm., $FeSO_4,7H_2O$ 0·01 gm., glucose 40 gm., casein hydrolysate solution (Mueller) 2 ml., distilled water to 1 litre.

The growth of *Penicillium notatum* was excellent in this medium, which was sterilized by autoclaving at 120° C. for twenty minutes, and after about seven days at room temperature a compact layer had been formed which completely covered the surface of the medium in the culture vessels. But, if after sterilization the medium was inoculated with *Esch. coli*, incubated at 37° C. for 24 hours, and autoclaved again at 120° C. for twenty minutes, the rate of growth of the fungus was found to be greatly reduced. Not until about seven days after inoculation could signs of growth be observed in the form of small, scattered, star-like, white figures around the wall of the vessel at the level of the surface of the medium. The later growth was also very slow.

The differences in the sugar concentration and the *p*H, respectively, between the medium in which *Esch. coli* had been cultivated and the original medium were not significant, and the reduction in the rate of growth can therefore not have been due to any variation in these respects. It was also proved that with the exception of the inoculation with *Esch. coli* the treatment of the medium (incubation at 3 and autoclaving) did not cause the inhibition growth. Since all the substances necessary for nor growth were present, some fungistatic factor, w also was thermostable, must have been produced

This fungistatic factor can be produced in o media also, for example, broth, but not to the s extent as in that stated above.

The factor in question was found to be without effect in the assay of penicillin by the cylinder-p method (modified according to Wiedling[11]). It t differs from penicillinase not only in its ther stability, but also in that its effect on the product of penicillin is caused by a reduction in the rat growth of the fungus and not by actual destructio the penicillin. The thermostability of the factor distinguishes it from most other bacterial fungistat which usually are thermolabile[12].

A New Occurrence of the Electronic Phase Velocity

STARTING with the Lorentz equation:

$$\frac{d}{dt}\,(m\mathbf{v}) = e\,\left\{\mathbf{E} + \frac{[\mathbf{vH}]}{c}\right\} \quad . \quad . \quad . \quad ($$

we have, after scalar multiplication by **v**, which at right angles to the vector product [**v**,**H**],

$$\frac{d}{dt}\,(\tfrac{1}{2}mv^2) = e\mathbf{vE} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad ($$

Replacing **E** in terms of φ and **A**,

$$\frac{d}{dt}\,(\tfrac{1}{2}mv^2) = -\,e\left(\mathbf{v}\nabla\varphi + \frac{\mathbf{v}\dot{\mathbf{A}}}{c}\right); \quad . \quad . \quad ($$

where **A**, the vector potential, satisfies

$$\mathbf{H} = \text{curl}\,\mathbf{A} \text{ and } \nabla A + \dot{\phi}/c = 0 \quad . \quad . \quad . \quad ($$

We next write in (3) for its rearrangement

$$\mathbf{v}\nabla\varphi = \frac{d\varphi}{dt} - \dot{\phi}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad ($$

so that the total energy changes at the rate

$$\frac{d}{dt}\,(\tfrac{1}{2}mv^2 + e\varphi) = e\dot{\phi} - \frac{e\mathbf{v}\dot{\mathbf{A}}}{c}. \quad . \quad . \quad . \quad ($$

Now, using (4), this may be written

$$\frac{d}{dt}\,(\tfrac{1}{2}mv^2 + e\varphi) = -\,ec\left(\nabla\mathbf{A} + \frac{\mathbf{v}}{c^2}\dot{\mathbf{A}}\right) \quad . \quad ($$

Next, let us seek the consequences of supposin $(\tfrac{1}{2}mv^2 + e\varphi)$ to be constant, both in space and tim This means, from (7),

$$\nabla\mathbf{A} + \frac{\mathbf{v}\dot{\mathbf{A}}}{c^2} = 0\,; \quad . \quad . \quad . \quad . \quad (8$$

so

$$m\mathbf{v}\dot{\mathbf{v}} + e\phi = 0. \quad . \quad . \quad . \quad . \quad (9)$$

dding (9) to ec times (8) we have:

$$\mathbf{v}\left(m\dot{\mathbf{v}} + \frac{e\dot{\mathbf{A}}}{c}\right) + ec\left(\nabla\mathbf{A} + \frac{\dot{\phi}}{c}\right) = 0. \quad . \quad (10)$$

ut, by (4), the last bracket vanishes. Thus, aside om the trivial result $\mathbf{v} = 0$, we are left with

$$\dot{\mathbf{p}} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

here

$$\mathbf{p} = m\mathbf{v} + \frac{e\mathbf{A}}{c} \quad . \quad . \quad . \quad . \quad (12)$$

is the sum of the mechanical and electromagnetic omentum associated with each particle. Thus, in der for the energy of a particle to be conserved, (11) ust hold good; but this need not mean that both $\dot{\mathbf{v}}$ d $\dot{\mathbf{A}}$ must separately vanish. Thus $\dot{\phi}$ need not be ro in (9), so that $\nabla\mathbf{A}$ need not be zero. Then (8) ay be regarded as having a non-trivial solution. the variable part of $\mathbf{v}$ is small compared to the art which is constant in time and space, a close pproximation to this solution is the plane wave

$$\mathbf{A} = \psi\,(\mathbf{s} - \mathbf{u}t), \quad . \quad . \quad . \quad (13)$$

here

$$\mathbf{u} = c^2/\mathbf{v}, \quad . \quad . \quad . \quad . \quad . \quad (14)$$

is any function of the argument shown and $\mathbf{s}$ is ne vector distance.

Now if the beam is moving in a straight line, url $\mathbf{u} = 0$. Provided $\mathbf{A}$ is directed along $\mathbf{s}$, we shall hen have curl $\mathbf{A} = 0$. But this means no Poynting ector. Hence, for a beam of electrons moving with early uniform velocity in a straight line, electronic aves of a kind are predicted. These are A waves, et carry no energy away provided A is directed angential to the path of the electrons, which is also 's direction of propagation with wave velocity $\mathbf{u}$ nd group velocity $\mathbf{v}$.

In view of experiments leading us to infer for lectronic waves properties precisely the same as hose postulated for the electronic A waves, our discovery of these is perhaps not to be regarded as ortuitous.

If we regard the arbitrary part of the phase as governed by the experimental result

$$\lambda = h/mv, \quad . \quad . \quad . \quad . \quad . \quad (15)$$

ur solution may be written in the form

$$\mathbf{A} = \mathbf{s}_1\,\psi\left(\frac{mc^2}{\hbar}\,t - \frac{mvs}{\hbar}\right), \quad . \quad . \quad (16)$$

where $\hbar = h/2\pi$; $\mathbf{s}_1$ is a unit vector along $\mathbf{s}$.

In order to obtain A as a wave of velocity c, such s is obtained in atomic and wireless radiation, it is ecessary to depart from the principle that $\frac{1}{2}mv^2 + e\phi$ s constant. The terms on the right-hand side of (6) hen yield radiation of known type, of which the A-dependent part may travel to great distances; but before such result is obtained it is necessary to sum over all particles present in the field.

I should like to thank Prof. H. T. Flint for his interest and for suggesting the title of this note.

Chromatography of Two Solutes

THE communication by Drs. Offord and Weiss[1] is of particular interest to me, as I am just publishing a paper on the same subject, though with different results.

Using the same definitions, we have the adsorption isotherms

$$q_1 = f_{(c_1c_2)} \quad , \quad q_2 = g_{(c_1c_2)} \,;$$

whence it follows from de Vault's equations[2] that

$$\frac{df_{(c_1c_2)}}{d_{c_1}} = \frac{dg_{(c_1c_2)}}{d_{c_2}} = \frac{v}{x} \quad \text{(see Offord and Weiss's equation 2)} \qquad (1)$$

Equation 1 defines the relationship between c_1 and c_2 in that part of the chromatogram where the concentrations vary. But without a complete solution of this simultaneous differential equation, no useful deductions can be drawn. Offord and Weiss's equation 3 for v/x which, if correctly deduced, should read:

$$v/x = g'_{(c_2)} -, \text{ etc.} \qquad (1.1)$$

unfortunately has no meaning, as it refers to definite sets of c_1 and c_2 (defined by eq. 1) and, without an integration, there is no way of knowing which value of c_1 belongs to any given c_2.

Fortunately, the only adsorption isotherm which offers a theoretically founded relationship between the amounts of multiple solutes adsorbed and in solution—the Langmuir isotherm—does permit of a solution of equation 1, resulting in a linear relation between c_1 and c_2.

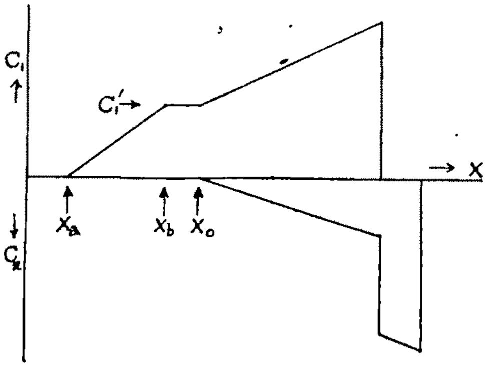
Taking $f = a_1c_1/(1 + b_1c_1 + b_2c_2)$ and $g = a_2c_2/(1 + b_1c_1 + b_2c_2)$ where $a_1 > a_2$, the solution of equation 1 is:

$$a_1b_2c_2 = a_2b_1c_1.\lambda - (a_1 - a_2)\lambda/(1 + \lambda), \quad . \quad (2)$$

where λ is an integration constant obtainable from equation 2 by inserting the initial conditions $c_1{}^0$ and $c_2{}^0$. This gives a quadratic equation with a positive and a negative root for λ. One of these applies according to whether dc_1/dc_2 is positive (trailing boundary of the less adsorbed material) or negative (forward boundary of the more strongly adsorbed material).

Equation 2 makes it possible to calculate exactly and in detail every stage in the development of the chromatogram, and this has been done in the paper referred to. After the disappearance of the original constant levels, the distribution is shown in the diagram (where diffusion phenomena which would reduce the sharpness of the front boundaries are not considered).

The chromatogram shown has three distinct parts: a pure frontal band of pure solute II, a mixed band,



and a rear band of pure solute I. The statement by Offord and Weiss that the same solute may appear both in the front and rear bands if its concentration greatly exceeds that of the other solute certainly does not apply to this type of isotherm. This phenomenon is not general, but occurs only when the two isotherms intersect, and when thus the same solute is more strongly adsorbed at low concentrations (rear) and less adsorbed at high concentrations (front).

Offord and Weiss's equation for the amount of pure solute in the tail band does not, as claimed, represent the total content, but only the amount between x_a and x_b. Consequently, their equation 7 for the volume of pure solvent required for total separation is also erroneous.

If the tail band containing pure solute I were not fed constantly from the mixed band, its forward edge would travel down the column in accordance with the equation:

$$\Delta v / \Delta x_0' = f_{(c_1' o)} / c_1' \quad . \quad . \quad . \quad . \quad (3)$$

(see Weiss[3]), while the rear end of the mixed band is given by

$$\Delta v / \Delta x_0 = f'_{(c_1' o)} \overset{c}{=} g'_{(c_1' o)} \quad . \quad . \quad . \quad (4)$$

where $f'_{(c_1' o)}$ and $g'_{(c_1' o)}$ stand for the complete differentials $[df/dc_1]_{c_2=0}$ and $[dg/dc_2]_{c_2=0}$ respectively.

To maintain a continuous chromatogram the amount fed into the tail band must therefore be

$$\Delta m_1 = (\Delta x_0 - \Delta x_0') \cdot f_{(c_1' o)}\,; \quad . \quad . \quad (5)$$

whence it follows that, for complete separation, the volume V of solvent required is given by

$$m_1 = v^0 \cdot c_1^0 = V \cdot \left(\frac{f_{(c_1' o)}}{g'_{(c_1' o)}} - c_1' \right); \quad . \quad (6)$$

while the minimum length of column required for complete separation is

$$L = V / g'_{(c_1' o)} = m_1 / (f_{(c_1' o)} - c_1' \cdot g'_{(c_1' o)}) \quad . \quad (7)$$

Equations 6 and 7 are, however, almost without practical value unless c_1' is known, and this can so far be calculated for Langmuir isotherms only, where

$$c_1' = (a_1 - a_2)/a_2 b_1 (1+\lambda) = \delta / b_1 (1+\lambda), \quad . \quad (8)$$

where $\delta = (a_1 - a_2)/a_2$. This leads to

$$V = m_1 b_1 (1+\lambda)/\delta^2 \text{ and } L = m_1 b_1 (1+\lambda+\delta)/a_2 \delta^2. \quad (9 \text{ and } 10)$$

It follows from equation 2 that λ assumes simple values when $b_1 c_1^0 \gg \delta$ and when $b_1 c_1^0 \ll \delta$. In the first case, corresponding to solutes difficult to separate, $\lambda = a_1 b_2 c_2^0 / a_2 b_1 c_1^0 = \text{approx. } c_2^0 / c_1^0$; whence

$$V = \sim b_1 (m_1 + m_2)/\delta^2\,; \quad . \quad . \quad . \quad (11)$$

showing dependence on the combined amount of solutes to be separated. In the second case, where the adsorption intensity is comparatively low, $\lambda = \delta / b_1 c_1^0$ and consequently, as $\lambda \gg 1$,

$$V = v^0 / \delta, \quad . \quad . \quad . \quad . \quad . \quad (12)$$

thus linking up with Wilson's equation[4] for non-developing bands.

Anomalous Inactivation of Heavy Metal Antifouling Paints

THE inactivation of antifouling paints in th neighbourhood of an exposed steel surface, referre to by Young and Seagren[1], has often been encountere by investigators of the Marine Corrosion Sub-Committee. Fouling on one or both sides of an unpainte 'holiday' (the location of the fouling being determine by the direction of tidal flow) is invariably accompanied by rust deposits in the fouled areas.

The cause of this inactivation is probably no connected with the interaction of the base metal wit the heavy-metal poison; indeed the phenomeno has been observed by us in paints which rely largel or entirely on organic poisons. The following explanation, based on the work of Dr. U. R. Evans[2] o metallic corrosion in salt solutions, appears to offe a sounder basis for interpreting the observations.

At some portions of a bare steel surface exposed t sea water, the metal becomes anodic to the surrounding (in this case painted) area, and from the anodi regions ferrous ions pass into solution. These diffus outwards and in the presence of free oxygen and alkal arising from the cathodic reaction, form ferri hydroxide which becomes deposited as a rust coating In still water the ferric hydroxide is formed in th boundary region between the anodic and cathodi areas, but in the presence of a water current th deposition of rust will spread in the direction of th current.

The antifouling properties of the coating will b affected in several ways by this process. In presenc of the alkaline cathodic product, though the rosi matrix of the antifouling paint may be more rapidl dissolved, the solubility of the copper will be depressed in the presence of free OH′ ions. It has bee shown by extensive unpublished work in Grea Britain and in the United States[3] that for a coppe paint to be effectively antifouling, it must releas its copper at a clearly defined minimum rate into th sea water; if copper leaches out at a satisfactory rate under normal conditions, the effective toxicity of the paint will be greatly reduced in presence o alkali. The deposition of rust in the pores of the pain (which may be increased by cataphoretic action on the positively charged colloidal ferric hydroxide) wil also tend to reduce the loss of copper from the surface.

In the initial stages of their life, many antifouling paints show an excessively high rate of loss of copper —this is particularly true of metallic copper paints— and the early freedom from fouling in Young and Seagren's experiments is not at all surprising. The production of alkali in cathodic regions will only occur over the painted portion of the plate when the paint is sufficiently swollen after long soaking to be electrolytically conducting; alkali-softening of the paint, starting from the edge of the bare steel area, will spread outwards and progressively inactivate greater and greater areas of the painted surface.

There is thus no need to invoke the authors' hypothesis of inactivation by organic iron complexes; it is doubtful if the conditions are such as to encourage their formation. Dr. M. F. Spooner found that the pH of slime films in our experiments was never lower than 7·5; the rust on the paint surrounding a bare metal 'holiday' appears within a day or two even on synthetic resin paints, which form slime films only a few microns in thickness at this early stage. A similar type of rust deposit on painted steel panels occurs in sodium chloride solution in the laboratory;

nd the mechanism of inactivation suggested above ppears quite adequate to explain the effects observed.

The limited inactivation near an *insulated* steel lock is therefore due to the fact that the cathodic as well as anodic areas will be on the bare steel, so hat the above conditions for extensive deposition of rust on the adjacent paint surface do not exist; nd inactivation of the antifouling composition will be restricted to the painted area immediately adjacent o the edges of the insulated plate.

Amino-quinazolines

IN a journal which has recently reached us, Dewar[1] reports the preparation of the 2-amino- and 4-amino-quinazolines. In the course of work on the amino-benzadiazines and their sulphanyl derivatives carried out in these laboratories, we had also prepared the amino-quinazolines, but in some respects our results differ from those described by Dewar. Thus we obtained good yields of 2-amino-quinazoline from guanidine nitrate and O-amino-benzaldehyde, a method stated by Dewar to yield only traces of the desired product. The 4-amino-quinazoline we prepared by amination of the corresponding chloro-compound.

Our melting points for the substances are somewhat higher than reported by Dewar, the 2-amino- and 4-amino-quinazolines having melting points of 204° and 272° respectively.

The bases were coupled with sulphonyl chloride to give 2-sulphanilyl-quinazoline (m.p. 286°) and 4-sulphanilyl-quinazoline (m.p. 255·5°), but the compounds are too insoluble to have chemotherapeutic activity.

Full experimental details of the work will be published elsewhere.

Influence of Sulphur Oxides on the Luminosity of Coal Gas Flames

IN the course of an investigation into the oxidation of sulphur dioxide in combustion reactions, forming part of a programme of work being carried out for the Boiler Availability Committee, some interesting observations have been made on the luminosity of coal-gas flames to which sulphur oxides had been added.

When sulphur dioxide was added in small quantities to a luminous smoky flame, the luminosity decreased and completely disappeared after about 5 per cent by volume of sulphur dioxide had been added. The flame showed a purple colour, and when a cooled funnel was held above the flame a yellowish-white deposit collected. Physical and chemical tests showed this to be sulphur. Spectroscopic examination of the flame revealed that a series of bands was present which appeared to be due to S_2 molecules. 5 per cent of sulphur dioxide added to a normally aerated bunsen flame shortened the outer cone and imparted a purple colour to this normally dark-blue region.

The addition of sulphur trioxide, on the other hand, increased the luminosity of coal-gas flames. When the port on the burner was adjusted so as to give an almost luminous flame, the introduction of 0·1–0·2 per cent by volume of sulphur trioxide brought about an immediate increase in luminosity. The same effect is observed in an aerated flame but the amount of trioxide required was of the order of 1 per cent. Whether this increased luminosity is due to emission from carbon particles produced by reactions involving the sulphur trioxide and the hydrocarbons present in the gas or to some other cause has not yet been established.

A detailed account of these results and of the behaviour of sulphur oxides in combustion reactions will be published shortly.

Distribution of Vanadium, Chromium, Cobalt and Nickel in Eruptive Rocks

THE similarity, pointed out by P. H. Lundegårdh in a recent communication[1], between the amounts of the above trace elements in the normal series of igneous rocks from Eastern Upland, Sweden, and those in the corresponding members of the suite of rocks which we have analysed from the Skaergaard Intrusion, East Greenland[2], is of considerable interest in view of the differences between the two series of rocks. In describing our results, we offered tentative explanations of the observed variations in the trace constituents, based largely on V. M. Goldschmidt's earlier work, and we shall look forward to Lundegårdh's further treatment of the problem in view of his new data from Sweden.

In the meantime, it may be of interest to record some data, recently obtained, which indicate the actual location of the trace constituents in some of the minerals which make up certain of the Skaergaard rocks. From these data, we select the following for olivines and clino-pyroxenes separated from rocks previously analysed in bulk and quoted by Lundegårdh.

PERCENTAGE OF CERTAIN CONSTITUENTS IN OLIVINES AND CLINO-PYROXENES SEPARATED FROM ROCKS OF THE SKAERGAARD INTRUSION.

	Olivines from:		
	Gabbro picrite	Olivine gabbro	Hortonolite ferrogabbro
V	0·003	—	—
Cr	0·1	—	—
Co	0·01	0·01	0·01
Ni	0·1	0·04	0·001
Fe_2SiO_4	19	37	60

	Clino-pyroxenes from:		
	Olivine gabbro	Middle gabbro	Hortonolite ferrogabbro
V	0·01	0·01	0 003
Cr	0·04	—	—
Co	0·004	0·006	0 004
Ni	0·008	0·005	—
$FeSiO_3$	19	36	50

In the table a dash indicates that the amount present is less than the sensitivity of the spectrographic method employed, namely, vanadium 0·0005 per cent, chromium 0·0002 per cent, cobalt 0·0002 per cent, nickel 0·0002 per cent. The order in which the rocks are given is the order of their formation.

Plagioclase felspars have also been separated and other minerals are in the process of being separated and analysed.

The microscopic and field evidence indicates that the rocks selected for analysis represent, as closely as can be expected under natural conditions, crystal fractions from a single slowly cooling magma. The amounts of the trace constituents are in this case apparently controlled by the ease with which the trace elements enter the various crystal phases, and we must turn to the crystal chemist for a detailed consideration of the factors involved. The rocks of the Skaergaard Intrusion and the minerals composing them provide data on the kind of changes in the trace constituents which occur as a result of strong fractional crystallization differentiation of basic magma, and this should form a useful starting point in attempts to understand the variation in the trace constituents of rock suites having a more complex petrogenetic history.

Possible practical applications of results such as these include the diagnosis in soils, purely from a geological examination, of deficiencies or excesses, which may be of importance for problems of plant and animal nutrition.

Economy in Sampling

The method described by Haldane[1] for estimating the fraction p of a population having the attribute A is a particular instance of a more general theory which has been used in this department and elsewhere since 1943.

The statistical methods of assessing trial results in use before the War were for the most part developed in connexion with biological problems, where there is often present a limitation not found in other fields, namely, that the sample size for a proposed experiment must be determined in advance, before the experiment is actually begun. When such a limitation is unnecessary, it is found more efficient usually to plan a statistical *procedure*, and an associated test, for determining the question at issue.

For example, if we want to compare two designs, A and B, of an instrument, with regard to their comparative effectiveness, the classical procedure would suggest A be tried m times and B be tried n times, under similar conditions, and the numbers of successes observed for each design:

	1 Success	2 Failure	3 Total
Design A	a	c	m
Design B	b	d	n
Total	r	s	N

If we assume that, under the given conditions, A has a constant probability of success p_1 and B has constant probability of success p_2, then the null hypothesis $p_1 = p_2$ can be tested by a method which I have developed, or by a method due to Fisher[2], which, on the null hypothesis, associates with the above table a probability $m!n!r!s!/N!a!b!c!d!$. These tests correspond to the procedure in which column 3 of the table is fixed in advance, and columns 1 and 2 are filled in from the experimental results.

We may, however, be able to fix, say, column 2 in advance, and allow the experimental results to determine 1 and 3. In this case, by a procedure exactly analogous to Fisher's, we find that the probability on the null hypothesis associated with the above table is $(m - 1)!(n - 1)!r!s!/(N - 1)!a!b!(c-1)!(d - 1)!$, and we can construct a significance test accordingly. For large m and n there is a continuous approximation, which takes the form of the variance ratio function F, analogous to the χ^2 approximation in the classical case. There is also a correction for continuity, analogous to that of Yates[3].

In order to compare the efficiency of this test with that of the classical procedure, we have to compare at the mean sample size, since the actual sample size with the new procedure is not fixed. Consideration of the power for given mean sample size then shows that, when at least one of the two probabilities involved is small, the new test is much more powerful than the classical test. The power-ratio is not fixed, but for suitable values of p_1 and p_2 may increase without limit.

Similar considerations can be applied to all other kinds of statistical test. Broadly speaking, when the statistician was asked by the experimenter the question "How many items should I take for my sample?" it was often difficult to give a reasonable answer, since this would often depend on knowledge which could only become available after the result was known. By making sample size one of the variables which are determined in the course of the experiment itself, it is possible for the statistician to tell the experimenter: "If you follow this procedure, you will determine the issue involved just as soon as your results allow". From a passive role involving static planning and subsequent testing of results obtained, statistical theory acquires an active role, entering into the experimental process itself.

In developing tests for other situations, it is found that the statistical theory involved is closely connected, on one hand with the classical theory of games, as studied by de Moivre[4], Laplace and others, and on the other hand, with the theory of diffusion processes. In particular, the statistical tests involved in many consumer's inspection problems are direct generalizations of the classical problem of the "Ruine des Joueurs", in the qualitative case, while the continuous measurement case corresponds to a linear diffusion problem with fixed absorbent boundaries.

This work has been carried out as part of the programme of the Ministry of Supply.

IS HUMAN SPEECH GOOD ENOUGH?*

By SIR RICHARD PAGET, BART.

THE answer to the query in the title depends on what we mean by human speech—and what we ean by good enough!

Very few ideas can be directly expressed by sounds; und itself is not an essential of human speech—we n speak (to ourselves) and express meaning simply making the motions of 'articulation', without pro- cing any sound; deaf people who have learnt the t of lip-reading can understand such silent speech, watching the gestures of articulation. It is there- re the gestures rather than the sounds of speech hich carry meaning; the functions of sound, in eech, are to enable its meaning to be identified by ear.

The gestures of articulation are fundamentally ntomimic, and this pantomime is made audible by e vibration of our vocal cords—to produce 'voiced' unds; or by blowing air through our vocal cavities -to produce the 'unvoiced' speech sounds. The stures of articulation modify these voiced or un- iced sounds in much the same way as the manipula- on of the keys, slides, etc., of a musical wind strument modify its sounds; just as a skilled ombone player could, with his eyes shut, visualize e gestures of another trombone player by simply stening to his playing, so we, subconsciously, recog- ize a speaker's gestures of articulation by listening his speech. The voiced and unvoiced sounds of eech are the relics of the original emotional nguage of mankind.

The origin of mouth pantomime may be recognized the born deaf; they naturally express their ideas y bodily pantomime—mainly hand pantomime— hich they enrich with facial expression. Some form f emotional expression is essential if we are to succeed making our fellow men think as we want them to.

The combination of hand pantomime and emotional ounds eventually produced speech because of the arwinian "imitation or some kind of sympathy" etween the movements of man's hands and mouth Darwin, "The Expression of the Emotions" (1872), . 34). Alfred Russel Wallace, in an article in the *ortnightly Review* during 1895, wrote: "Speech was ormed and evolved . . . by men and women who elt the need of a mode of communication other than esture only. Gesture-language and word-language oubtless arose together, and for a long time were sed in conjunction and supplemented each other".

It follows that as primitive man pantomimed, his outh—without his knowledge—took part in the antomime; the result must have been a 'gabble' of peech-like sounds due to the changes of the volume nd size of orifice, and the constrictions and stoppages f the vocal cavities, and to the changes of the tone f voice caused by changes of emotional state.

In general pantomime, the sequence of gestures does not represent a succession of words—it describes ctions or states as a whole. This stage of general antomime, accompanied by mouth gabble, may have been man's normal mode of expression during the greater part of his million or half-million years of prehistoric development.

According to Prebendary Albert Smith, chaplain to the Royal Association in aid of the Deaf and Dumb, the uneducated born deaf still do not think in the same way as hearing people. They have no signs comparable to our words; their impressions are generalized (like their pantomime) and they cannot define anything, because they have no units with which to define. This is a point of the utmost importance. It distinguishes the career of primitive man from that of *Homo sapiens*, the analytical thinker of the last six or eight thousand years. At some point in his unrecorded history, man must have hit upon a new way of mentally handling his impressions; he separated them into categories, such as shape, colour, number, etc., and symbolized each separate element by a distinctive pantomimic sign. He could then begin to play with units of thought, transposing and recombining them in his mind, so as to arrive at new combinations and inventions.

This is admittedly hypothesis; but it offers a reasonable explanation of man's sudden and rapid advance in civilization. It was not man's brain which suddenly changed, but his way of using his brain.

The discovery, by primitive man, of the new method of analytic symbolism must have led, by slow degrees, to a new type of sign language composed of separate signs equivalent to modern words, performed in a more or less logical order, such as the Red Indian sign language.

The gesture theory of speech has recently received powerful support from Prof. Alexander Jóhannesson, of Reykjavik University, Iceland, who sent me a statement of which the following is a summary: In a twelve-years study of the Icelandic language (old and new) Prof. Jóhannesson examined every Indoeuropean root and found the etymology of about 20,000 words. It became gradually clear that a great many roots showed a primary meaning which was in accordance with the nature of the sound. In 1943 he published (in Finnish) his book "On the Primitive Language of the Indoeuropean People", in which he explained about 25 per cent of the whole Indoeuropean material and showed that a great part was due to imitation by the speaking organs of the movement of the hands. Having written about half of his book, my "Human Speech" came into his hands; he was delighted to see that, by studying the nature of the sounds, I had come to nearly the same results as he had by comparative philology. He was encouraged by my work and was now able to explain the majority of the Indoeuropean roots as gesture; he was highly satisfied to find the gesture theory confirmed also in Hebrew (in certain sound-groups he easily explained 60 per cent). He believes that my gesture theory will be of great importance for philology, and regards the problem of the birth of language in its chief principles as solved. Philology will take its place among the other sciences in the evolution of man. He is convinced that an international auxiliary language—which will be much needed in the near future—can only have a prospect of success if constructed in accordance with this new knowledge.

Here I must make one disclaimer: I did not originate the gesture theory; this was, I believe, originally propounded by Mr. J. Rae, of Honolulu, in three articles written, in 1882, for the *Polynesian* newspaper. Mr. Rae's work was referred to by Prof. Max Muller at a Royal Institution lecture on the science of language in 1863. His theory was not then described, but the British Museum had a bound volume of the *Polynesian* and the articles were reprinted as an appendix to my "Human Speech".

As to the question, "Is human speech good enough?", the answer, considering the appalling confusion into which this world has been thrown, largely by muddled thinking and perpetual misunderstandings, must surely be: No! We needed something more precise—more quantitative and less ambiguous—something which will advance human mentality as mathematics has advanced physical science and technology. The mystery and magic of human speech need no longer block the way. The late Prof. Otto Jespersen ("Mankind, Nation and Individual from the Linguistic Point of View", 1925) emphasized the duty of improving language for the sake of future generations, and said that "that language is best which, at every single point, is easiest to the greatest possible number of human beings".

---

* Substance of Friday discourse at the Royal Institution, delivered on March 23.

English—though probably the best language yet evolved—is still very imperfect. Thus: 'to understand' does not mean 'to stand under'; 'to learn by heart' does not mean 'to learn by means of the heart'; 'to undertake' does not mean 'to take under'. As to changes of articulation in course of time, the so-called 'sound shifts' are mainly only 'exhibits' of the principle of 'least effort'. The organs of articulation tend to make their gestures easier to perform; voiced sounds become unvoiced, tongue postures are shifted to accommodate the accompanying consonant gesture, etc. Generally speaking, although 'least effort' is ever present, the significant gestures tend to be preserved, though the manner of making them may be modified.

As to verbal inflexions, English has discarded all the Germanic forms except that of the third person singular of its verbs—this hissing 'relic of barbarism' should be removed! Grammar itself is a relic of barbarism; it probably had its origin in sign language. Thus, it is easy to combine, say, the sign for 'come' with the finger signs for 1 or 2 or many, so as to sign one person come, two come, or many come. Mouth gesture cannot imitate these combined hand gestures; new arbitrary mouth gestures are substituted, and language becomes burdened with singular, dual and plural forms of its verbs.

Both English language and spelling need reform. Prof. Gilbert Murray, who is president of the Simplified Spelling Society, in a letter to me wrote: "I very much agree with you that English is so nearly a good language that it really ought to be looked after". If all children were taught something about the present *imperfections* of English, and were initially taught a rational system of spelling, reform would come of itself in another generation; if all children (throughout the world) were taught sign language—as a form of play—there would be one auxiliary international language available within the next twenty years. The British Commonwealth and the United States should join in appointing two English-speaking commissions, one to study the language, the other the spelling. Sufficient unification of pronunciation could easily be achieved through educational talking films and broadcasting.

The following are suggested as essential requirements: (1) Audibility. This implies that the unvoiced speech sounds should be eliminated, as being utterly inferior in audibility and in musical and emotional value. Also that accuracy of articulation should be considered as important as finger technique is in the playing of musical instruments. (2) Every word should be the result of a gesture of articulation which is pantomimically related to the meaning of the word. (3) Every word should be invariable in its form, and capable of use as any part of speech—as in Chinese. (4) Every root word should be monosyllabic. (5) The word order should be strictl logical—it is absurd to invert the word order t denote a question (as in English). (6) Homophone should be eliminated. (7) The spelling should b systematic—with a separate alphabetical symbol fo each separate sound.

The development of an international auxiliar language on these principles has been carried near t completion by Mr. Kenneth Littlewood. It is name 'Monling', and was expected to be ready for th printer shortly. The sentence "The best language that which is easiest to learn and use" becomes, i 'Monling', "Ling 't top pai ken ad ploi il klar to bon"—where ' represents the English indefinit vowel, like the 'e' in "the king" or the 'a' in sofa

---

CHEMOTHERAPY OF TUBERCULOSIS

By Dr. M. A. SOLTYS

University of Cambridge

SINCE Ehrlich's discovery of 'Salvarsan' there hav been several attempts to seek a chemotherapeuti drug for the treatment of many infectious disease Of all the chemical substances studied in the chemotherapy of tuberculosis, calcium and gold compound have probably attracted more attention over a longe period of time than any others. Maver and Wells from their intensive investigations, came to th conclusion that calcium does not support the conception of a favourable influence on the course o tuberculous infection, nor does it appreciably increas the calcium content of blood and tissue, and n specific significance has been proved as yet fo calcium and its combinations.

Concerning gold therapy, Møllgaard in 1924 presented 'Sanocrysin' ($Au(S_2O_3)_2Na_3$) as a *magn sterilisans* in tuberculosis on the basis of anima experiments. He claimed that 'Sanocrysin' in th blood stream causes lysis and kills the bacilli. Afterwards that substance and several other gold compounds were studied by many workers, who claim that gold exerts no direct bactericidal action on th tubercule bacillus, but that it increases the resistanc through the reticulo-endothelial cells. According t them, gold appears to have found its place as reinforcing stimulant in the therapy of tuberculosis especially in cases in which collapse therapy is fo some reason or other impossible.

The year 1935 brought a great change in bacteria chemotherapy by the discovery of sulpha drugs After the first reports of Rich and Follis[2] on th inhibitory effect of sulphanilamide in experimenta tuberculosis of guinea pigs, two opposing opinion developed concerning this effect: first, that of the group of investigators who used exactly the sam technique as Rich and Follis and obtained simila results, especially with sulphanilamide and sulphapyridine; secondly, that of the group of investigator who chose other routes of administration and als different sulphonamide derivatives; but the drug tested were comparatively ineffective.

Striking results have been attained by Feldman an Hinshaw[3] and their co-workers in experimental tuberculosis of guinea pigs treated with the new diaminodiphenylsulphone compound 'Promin'. 'Promin', i its solid form, varies from white to light yellow an slightly hygroscopic. It is highly soluble in water, nd 40 per cent solutions are stable indefinitely and an be sterilized by heat. It is slightly bitter, but nall amounts may be mixed with the food of nimals without impairing their appetite or digestion. he guinea pigs tolerate a daily dosage by mouth of 00–400 mgm. over long periods. The experiments ndicated that in many of the animals 'Promin' either ad prevented the establishment of lesions or had aused their eventual disappearance. In the vast majority of the animals in the treated group that ad lesions, the histopathological characteristics of he disease process apparently were modified favourbly. The failure to demonstrate lesions of tuberulosis in a considerable number of the animals that vere treated, and the further fact that the disease in he treated animals was with few exceptions minimal nd non-progressive, indicate that the action of the rug was significant. Encouraged by the animal xperiments, 'Promin' has been used in the treatment of a few cases of tuberculosis in human beings. In nan, unfortunately, much lower dosage relative to veight may soon produce toxic effects, particularly æmolytic anæmia. In these few cases treated with Promin', it appeared, that outstanding success has not been attained in man with any dosage which is vell tolerated. In Great Britain, Tytler and Lapp[4] pplied 'Promin' locally to superficial tuberculosis esions in ten cases. The improvement in all cases was greater, or more rapid, than would have been expected by orthodox methods of treatment. These authors reported that Dr. G. T. Allerton, of Torquay, had been applying the drug to superficial lesions with much success.

In 1943, Kharash and Reinmuth reported on a derivative of N-(1-carboxyacylaminoethylthiomethyl) designated as 'Kharash 1048'. This substance had shown an inhibitor effect on the development of experimental tuberculosis in guinea pigs (Hinshaw and Feldman[5]). More recently, Petter and Prenzlau[6] have described their results with diazone (the disodium formaldehyde sulpho oxylate derivative of 4-4″ diaminodiphenylsulphone, a compound synthesized by Raiziss) in forty-four patients. All the patients received diazone for 120 days or more. The total daily dose was 1 gm. There appear to have been no serious reactions except some cyanosis and nausea in about one quarter of the patients. Signs of improvement were first noticed between the 45th and 125th days of treatment. In 60 per cent of the group, sputum became negative. The authors consider they observed marked improvement in 18 per cent and moderate improvement in 50 per cent of cases.

Thus 'Promin', diazone and other related compounds appear to possess in varying degree the striking power of restraining the development of experimental tuberculosis in guinea pigs; but it is recognized that experimentally induced tuberculosis in guinea pigs offers many contrasts with clinical tuberculosis in human beings, even though the causative organism is the same. Despite the lack of convincing evidence of the value of present chemotherapeutic substances in the treatment of human tuberculosis, further controlled clinical investigation is clearly desirable.

No review of progress in this sphere would be complete without reference to the observations made on antibiotic substances produced by micro-organisms such as penicillin, gramicidin, etc. The treatment with antagonistic organisms was initiated by Cantani (1885), who employed, with reportedly favourable results, an organism designated as 'Bacterium Termo'. Later, many papers on that subject were published announcing varying degrees of success. Recently, two papers appeared on the subject, one by the present writer[7], who obtained promising results *in vitro* with filtrate of culture of *Aspergillus Fumigatus* No. 367 N.C.T.C., grown on modified Czapek Dox medium, and a second published by Miller and Rekate[8], who found that the growth of a strain of the tubercle bacillus was inhibited by a green mould of the penicillin group which accidentally grew on a culture of the tubercle bacillus stored in an icebox. The negative effect of penicillin upon *Mycobacterium tuberculosis* has been reported by Sir Howard Florey and his school[9].

All possibilities for the treatment of the disease should be explored at the present time, when the number of clinical cases of tuberculosis is increasing daily in starving Europe. Even in Great Britain, where conditions of living are fairly good, Stocks[10] considers that for all forms of tuberculosis the cost of the War up to mid-1942 may be estimated at about 11,000 deaths. Research on the control and treatment of tuberculosis should be regarded as a matter of urgency at the present time, and it is difficult to understand why there has been no foundation of a separate institute for the study of tuberculosis.

However, as research continues and newer compounds are made available, what were perhaps previously considered to be futile efforts now assume a new importance and provide a measure of hope for believing that an effective chemotherapeutic agent will be eventually found.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS, 1945

THE fiftieth annual congress of the Union was held at Harpenden on July 7 at the invitation of the director of Rothamsted Experimental Station and by arrangement with the Harpenden Urban District Council. Before the presidential address was given the following sectional addresses were delivered: "Church Chests", by Edward Yates; "Trace Elements", by Dr. Winifred E. Brenchley; "Some New Weapons in the Geological Armoury", by P. Evans; "Country Planning", by C. S. Orwin; and "Fishing Research and the Overfishing Problem", by Dr. E. S. Russell.

Before the official business of the Union was transacted, Miss E. C. Busby, chairman of the Urban District Council, welcomed the congress. The new president, Dr. W. G. Ogg, director of Rothamsted Experimental Station, was then installed and gave an address entitled "Some Aspects of the Work at Rothamsted". Brigadier F. A. E. Crew presided. The presidential and sectional addresses will be published in full in Vol. 50, 1945, of the *South-Eastern Naturalist and Antiquary*.

Dr. Ogg mentioned that the Rothamsted work can be divided into two broad sections, one on soils and plant nutrition and the other on plant pathology and insect pests. Field experiments still occupy a prominent place in the programme. An important but little-known branch of this work is formed by the experiments conducted on farmers' own land in various parts of Britain; these provide information about the efficiency of fertilizers over a wide range of soil types and climatic conditions. Although field experimentation of this kind is done extensively in certain other countries, much of it is not above the 'demonstration' level. The number of the Rothamsted 'outside' experiments, the length of time they have been in progress and the fact that modern statistical technique is used, make them a unique series.

Modern experimental technique in conjunction with tests of the validity and significance of results was developed at Rothamsted as a corpus of knowledge by Prof. R. A. Fisher. It is used in all laboratory and field work at Rothamsted, and though barely twenty years old is standard in agricultural experimentation throughout the Empire, and is being increasingly adopted by progressive countries elsewhere. Efficient sampling surveys are a recent development of this technique and have been applied to various war-time activities, notably the formulation of a fertilizer policy. Philosophically, the new technique is of interest because it enables several factors to be examined simultaneously; as Fisher pointed out, if Nature were asked only one question she would often refuse to answer until some other topic was discussed.

A broad base is characteristic of the Rothamsted work; for example, biology cannot be excluded even from the study of soil physics. The availability of soil moisture for plants is bound up with organic manuring, including the use of leys; and cultivation cannot be studied without reference to roots. Fundamental work has been done at Rothamsted on the relation of the nodule bacteria to their host plants, and, with an increased staff, microbiological studies are being extended to include mycorrhiza and other problems having a community interest in more senses than one. From their very nature, the botanical studies on weeds in arable and grass-land have long had this interest.

The pathological studies include the intricate relationships between viruses and their insect vectors, and the not less obscure problems of the relation between husbandry and fungal diseases. The population aspect of insect behaviour has been a feature of the entomological work. The study of pest outbreaks is regarded as an appreciation of the changes in insect numbers in a locality. A distributional outlook has recently been brought to bear on problems of slugs and earthworms.

Collaboration between chemist and biologist in the department dealing with insecticides has brought about some remarkable achievements, including the establishment of an 'insect zoo', by means of which healthy insects for testing purposes are on hand the greater part of the year. In conclusion, Dr. Ogg said he would like to mention his hopes for the Department of Pedology now being formed. Soil classification is still in its infancy; in particular, the understanding of tropical soils is far from satisfactory. In the new department attention will be given to Colonial as well as to domestic soils. In this department, as in others, while preserving the best in the old must have an adventurous outlook on the new.

In July 1946 the Union hopes to hold its jubil congress of three or five days at Tunbridge Wells, t president-elect being Dr. Lancelot Hogben.

CARNEGIE CORPORATION OF NEW YORK

THE annual report of the Carnegie Corporati of New York for 1944 includes the report of t president, W. A. Jessup, prepared before his dea on July 9, 1944, and the report of the secretary a of the treasurer. The report of the president for t year ending September 30, 1944, compares the wor of the Corporation and the college thirty years ag and now, and stresses the extent to which America colleges and universities have, with their responsibilit for large endowments, found themselves engage indirectly or directly in many forms of business the ownership and control by the University Chicago of the "Encyclopædia Britannica" and the educational films of Eastman Kodak Co. an Electrical Research Products Inc. being an exampl One leading mid-western university has reporte contracts with Government agencies alone which in volve the expenditure of more money than the university proper has ever before expended in a single yea

The U.S. Government, through its Office of Scientific Research and Development, is currently expending more than 125,000,000 dollars in researc carried on chiefly by university scientific men. I recent years it has been a common practice for business and industrial organizations to unite in establishing foundations to enable them to work mor effectively with the colleges and universities. A distinctive feature of these relations of the college and the university to the public is the fact that Government, industry, private donors and foundations tend to specify the purpose for which the money is to be expended. This tendency to delimit the use of money is so common that only the exceptional college president or trustee can discuss the future of his institution in terms other than those of itemized additions to its programme. The combined endowments of colleges and universities to-day, as reported to the U.S.A. Office of Education, are more than 1,686,000,000 dollars, as compared with the 166,000,000 dollars at the turn of the century. At the present time the income of the Carnegie Corporation is about 4,500,000 dollars, while the receipts of American colleges in 1940 exceeded 630,000,000 dollars. Comparatively, the educational importance of the Corporation, as expressed in income and assets, is thus less than a generation ago. The reduction in income of the Corporation and the consequent reduction in grants made places a heavy burden on the trustees in appropriating the available income, and an examination of the list of appropriations during 1930–32 shows many grants for purposes which are no longer largely aided by the Corporation.

The report of the secretary contains a complete list of appropriations voted during the year 1944 totalling 5,873,215 dollars, the largest single grant being 5,000,000 dollars to increase the endowment of the Carnegie Institution of Washington, making that Institution the most heavily endowed scientific research agency in the United States, if not in the world. Its total endowment is now some 32,000,000 ollars. In addition to grants to various national mergency organizations, the Corporation voted 5,000 dollars to the Carnegie Endowment for International Peace for its educational work in the United tates, 40,000 dollars to the Council of Foreign Relations for its research and publication programme nd programme of regional committees, 34,000 ollars to the Institute of Pacific Relations and 0,000 dollars to the Foreign Policy Association.

The most ambitious single Corporation project oncerning the Negro has been the comprehensive tudy of the Negro in America conducted by a staff f research specialists directed by Dr. Gunnar Myrdal, which was published in two volumes in anuary 1944 under the title "An American Dilemma: The Negro Problem and Modern Democracy". The Corporation is endeavouring to regain and maintain lexibility of action from year to year in regard to he use of annual income, and the trustees are studying carefully what particular interests in the crucial imes to come may best constitute an effective programme for the Corporation. The report of the ecretary also includes a list of useful publications with the issue of which the Corporation has been oncerned.

THE COD

An important and detailed account of the biology and economy of the cod in the Newfoundland area has now become available*, based mainly on tagging experiments during 1931–35, both in inshore and in deep waters. The fishing industry in these regions has tended to lag behind those of other countries, not on account of lack of fish but because of the geographical position of Newfoundland, its small population and the absence of international trading facilities. With Norway and Iceland it is one of the three great centres of cod stocks, and it has also many other valuable fish.

The vast area of Grand Bank is the outstanding important portion of the Newfoundland area and is the key area for study. It should probably be regarded as containing the parent cod stocks with which many subsidiary stocks, including those found inshore, must be correlated. The study of the inshore cod should therefore on no account be separated from that of the cod on the banks, especially Grand Bank, and the deep-sea fishing should certainly be increased and not reduced, as the reservoir of fishes is on the banks. It is essential that both the inshore and bank fisheries should be intensively developed.

Reference for comparison is made to previous tagging experiments in the north-western Atlantic, Greenland and Iceland, the Faröe Channel and the north-eastern Atlantic. From these it appears that the cod (especially young cod) are comparatively circumscribed in their movements, the larger proportion of recaptures being made in or near the point of tagging. A few carry on extended migrations, and for spawning purposes there can be what amounts to mass migration from one region to another, the migration being necessary probably where good feeding and spawning conditions do not occur in the same region. The evidence supports the general hypothesis of the existence of local races of cod, most of which, in any event in the early years of life, remain within a region where a specific range of hydrographic and feeding conditions prevails, and in these there are characteristic and recognizable biological features, such as average number of vertebræ, rate of growth and fluctuations in good, moderate and poor years of hatching and survival of fry.

With regard to the Newfoundland tagging experiments, the main object of which was to obtain direct evidence of migrations, it was found that those tagged on the banks were much larger than those tagged elsewhere, the latter being mostly immature fish; 91·2 per cent of the inshore cod tagged were recaptured locally within 100 miles (and more than half of these within 10 miles), and only 8·8 per cent travelled distances of upwards of 100 miles. Only 1·5 per cent travelled more than 250 miles, a distance which might or might not take the cod into a zone of markedly different hydrographical conditions. With the bank cod the results were somewhat similar, but only 68·9 per cent were recaptured within 100 miles, and 31·1 per cent carried out migrations of more than 100 miles. Only 6·8 per cent exceeded 250 miles. Thus the bank cod carried on rather more extensive migrations than those from the inshore.

The fish up to about three years old are practically stationary, and up to the age of six or seven years, or even more, the average movement from the location would probably not exceed 200 miles. Thus there is every reason to believe that races of cod can occur. After maturity is reached, there appear to be increased migrations and intermingling. The maximum distance travelled by any recaptured cod was 560 miles, from Fortune, in the south of Newfoundland, to White Bay, in the north-east.

From the analysis of results of counts of vertebræ, and of first-year circuli in the fish scale, it is possible to recognize two main stocks: those growing to maturity in cold water (arctic type) and those in warmer ocean water (bank type) respectively. Mixing of these also takes place to a certain extent. The parent stock is probably that of the Grand Bank.

The majority of Newfoundland cod attain first maturity between the sixth and ninth year of life, at a size of 60–80 cm. In this they resemble Iceland and Norwegian cod rather than those from the North Sea, where maturity occurs at an earlier age than the above. Most spawning occurs in spring, but the season may extend from March to October. It is later in the north than in the south. The distribution of eggs and fry varies according to the type of season—whether or not the arctic current is of normal, or of greater or less than normal strength. Eggs and fry occur chiefly off the east coast of Labrador and Newfoundland and on the banks, the centre of density of distribution being rather more northerly in warmer years, and more southerly in colder years.

The fishery in general is most successful in colder rather than warmer years, although cod in more southerly regions are conditioned to water of higher temperatures than are cod of more northerly regions. In the latter, large catches are made in water of temperature 0° C. and even lower. The optimum temperature for large catches varies according to the region. It would be of advantage if information on prevailing and probable temperature conditions were made available to fishermen.

There is no sign of overfishing on the Grand Bank, which is probably capable of producing a higher yield. It is through the moderate development of trawling that progress is likely to be made.

---

* Newfoundland Gov. Research Bull. No. 14: A Biological and Economic Study of the Cod (*Gadus callarias* L.) in the Newfoundland Area including Labrador. By Dr. Harold Thompson. Pp. 160. (St. John's: Department of Natural Resources, 1943.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Engineer and Manager of the Warrington Water Undertaking—The Town Clerk, Town Hall, Warrington (endorsed 'Water Engineer and Manager') (August 24)

Senior Engineers (capable of designing high or low pressure water turbines, governors, or hydraulic valves) for work in the Midlands—The Ministry of Labour and National Service, Appointments Department. Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting D.1139.X (August 24).

Civil Engineering Assistant, and Junior Engineering Assistants (3, temporary)—The Clerk to the River Ouse Catchment Board, 7 Landcliffe Avenue, Harrogate (August 25).

Deputy Chief Drainage and Water Supplies Officer—The Executive Officer, Cheshire War Agricultural Executive Committee, Reaseheath, Nantwich (August 25)

Speech Therapist to the West Ham Education Committee—The Education Officer, Education Offices, 95 The Grove, Stratford, London, E.15 (August 25).

Research Assistant and Demonstrator in Zoology—The Acting Registrar, The University Leeds (August 25)

Lecturer in Botany—The Registrar, The University, Manchester, 13 (August 25).

Advisory Bacteriologist for the East Midland Province—The Principal, Midland Agricultural College, Sutton Bonington, Loughborough (August 25).

Technical Assistant in the Borough Engineer's Department—The Borough Engineer and Surveyor, Hornsey Town Hall, Crouch End, Broadway, London, N 8, endorsed 'Technical Assistant' (August 27)

Assistant Lecturer (temporary) in Geography—The Registrar, University College, Singleton Park, Swansea (August 28)

Head of the Technological and Science Department of the Wakefield Technical College—The Director of Education, Education Department, 27 King Street, Wakefield (August 29).

Librarian, at the College in Trinidad—The Secretary Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C 2 (August 31).

Mechanical Engineers for oil refineries (Ref No. C 2587.XA), Senior Research Engineers (Ref. No C.2022.XA), and Senior Mechanical Engineers for direction of work on the application of fuels and lubricants to i/c and other engines, and to various types of industrial work (Ref. No C 2667 XA), for home and overseas service with a large industrial organization—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting the appropriate Reference No. (August 31).

Gas Engineer and Manager—The Town Clerk, Town Hall, Southport, endorsed 'Gas Engineer and Manager' (August 31).

Strathcona-Fordyce Chair of Agriculture—The Secretary, The University, Aberdeen (August 31).

Psychologist (full-time)—The Chief Education Officer, County Hall, Taunton (September 1)

Psychiatric Social Workers (2, full-time, women) for Ealing and Harrow—The Clerk to the County Council, Middlesex Guildhall, Westminster, London, S.W.1 (September 1)

Lecturer in Physics—The Registrar, King's College, Newcastle-upon-Tyne (September 3).

Principal or Superintending Metallurgist with headquarters in London, a Senior or Principal Scientific Officer (preferably a physical chemist) for refractories, moulding sands, slags, etc., a Senior or Principal Scientific Officer (preferably a physicist) for instruments and automatic control in all fields of the Iron and Steel industry; and other posts of a more junior category for Chemists Physicists, Engineers and Metallurgists—The Secretary, British Iron and Steel Research Association, Steel House, Tothill Street, London, S.W.1 (September 7)

Probationary Assistant Lecturer in Physics, a Probationary Assistant Lecturer in Chemistry, and a Probationary Assistant Lecturer in Zoology—The Bursar and Acting Registrar, University College of North Wales, Bangor (September 10)

Probationary Assistant Lecturer in Agricultural Botany—The Bursar and Acting Registrar, University College of North Wales, Bangor (September 10).

Civil Engineer or Public Works Contractor's Agent to take control of an area in connexion with the employment of German P o.W. labour on construction of roads and sewers (Ref. No. E.1645 A), an Assistant Civil Engineer or Architect A.M I C.E or A.M.I.M and Cy.E or A.R.I.B.A., or equivalent, to act as assistant to the above (Ref. No. E.1735.A), and a Civil Engineering (Structural) Assistant (Ref. No. E.1462.A)—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C 2, quoting the appropriate Reference No. (September 14).

Academic Registrar—The Principal, University of London, Richmond College, Richmond, Surrey (September 15).

Chief Assistant (male) at the Government Archives, Salisbury, Southern Rhodesia—The Official Secretary to the High Commissioner, Rhodesia House, 429 Strand, London, W.C.2 (September 17).

Lecturer in Natural Philosophy at University College, Dundee—The Secretary, The University, St. Andrews (October 1).

University Chair of Anatomy, tenable at St. Bartholomew's Hospital Medical College—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (October 31)

Lecturer in Applied Mathematics within the Department of Natural Philosophy—The Secretary, The University, Aberdeen

Lens Workshop Instructor (full-time)—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

Superintendent of Applied Research—The Secretary, British Rubber Producers' Research Association, 19 Fenchurch Street, London, E.C.3.

Chair of Naval Architecture in the Faculty of Engineering of the Technical University, Istanbul—The Appointments Department, British Council, 3 Hanover Street, London, W.1.

Biology Master to teach the Zoology of the Science Sixth Fo to Open Scholarship standard and General Biology throughout School—The Headmaster, Blundell's School, Tiverton, Devon

Assistant to Chief Chemist—The Establishment Officer, M Marketing Board, Thames Ditton, Surrey.

Technical Assistant to the Advisory Bacteriologist, in co nexion with the National Milk Testing and Advisory Scheme. Southe Province—The Advisory Dairy Bacteriologist, National Institute Research in Dairying, Shinfield, Reading.

Lecturer (full-time) in the Applied Chemistry Department The Secretary, Northampton Polytechnic, St. John Street, Londo E.C.1.

Psychologists (part-time) for Child Guidance Clinics—The Cha man, Child Guidance Committee, County Hall, Chichester.

Lecturer in Engineering (subjects. Practical Mathematics a Engineering Science up to Ordinary National Certificate standard) The Principal, Day Continuation and Technical Schools, Falmout

Assistant (temporary, full-time) with First or Second Class Honou or Higher Degree in Mathematics, at the Bridgend Mining and Technic Institute and Technical School—The Director of Education, Coun Hall, Cardiff.

Teacher for Engineering Subjects, chiefly in the Day Juni Technical School—The Principal and Secretary, Harris Institut Preston

Lecturer (man or woman) in Mathematics and Physics at t Dudley Training College—The Secretary to the College Council, Educ tion Offices, St James's Road, Dudley.

Senior Mathematics Mistress to organize the subj throughout the School to University Entrance standard and Assistant Mistress to teach Physics or Biology, and Mathemati—The Headmistress, The Abbey, Malvern Wells, Worcs.

REPORTS and other PUBLICATION

FREEDOM OF SCIENTIFIC INTERCOURSE

SPECULATIONS as to the implications for material progress no less than for destructive purposes of the immense co-operative scientific effort that went to the evolution of the atomic bomb may tend to distract attention from some important issues relating to the progress of science itself. The profound secrecy in which this effort has been enveloped should emphasize the fact that for some six years the normal channels of communication between scientific men have been interrupted, and to restore such intercourse across national frontiers is the first step to stimulate the creative thought and exchange of knowledge and ideas upon which the progress of science finally depends. Sir Henry Dale has been prompt to point out, in a letter in *The Times*, that the preservation of civilization itself may now well depend on the fullest freedom of scientific intercourse. The abandonment of any national claim to secrecy about scientific discoveries, he suggests, must be a pre-requisite for any kind of international control such as will be indispensable if we are to use atomic energy to its full value and avoid the final disaster which its misuse might bring.

There may be no immediate opportunity for a national, still less for an international, exchange of scientific opinion, but the magnificent loyalty with which scientific workers have kept this greatest of war secrets cannot disguise the fact that those concerned, and their colleagues in science everywhere, are increasingly impatient for the revival of the world community of science to which Sir Henry referred. The importance of removing the restrictions on the scientists' liberty "to know, to utter, and to argue freely according to conscience" has already been stressed in the discussions on the development of scientific and industrial research in Britain, and has been emphatically endorsed in the report which Dr. Vannebar Bush recently presented to President Truman under the title "Science: the Endless Frontier". That report showed unmistakably that authoritative scientific opinion in the United States has come to recognize the need for more official methods of carrying on international scientific activity. Not merely the removal of war-time restrictions and hindrances, but also the positive encouragement of the exchange of knowledge and ideas by means of international scientific congresses, international fellowships and the like is strongly advocated.

Similar ideas have previously found expression in the report of the British Commonwealth Science Committee (see *Nature*, 152, 29; 1943) and Dr. Joseph Needham's proposals for an International Science Co-operation Service (*Nature*, 154, 657; 1944). They have been strongly emphasized in Britain, in the U.S.S.R. and in the United States in connexion with the recent visit of scientific workers to the Soviet Union to celebrate the two hundred and twentieth anniversary of the Academy of Sciences of the U.S.S.R. Co-operation with Russian men of science, said Sir Robert Robinson, in addressing the

Parliamentary and Scientific Committee, is absolutely necessary. Prof. E. N. da C. Andrade commented on the complete absence of suspicion, and on the value of personal contacts, particularly in view of the existing postal delays. With the opening of the Baltic and increased air service, an improvement in the postal services and in means of communication in general may be expected, but even so, as Sir Lawrence Bragg has emphasized elsewhere, it is often impossible to judge the value of a new theory or technique without personal visits or discussions. An interchange of advanced students would do much to increase understanding and to promote collaboration, and Prof. D. M. S. Watson on this same occasion referred to the evident desire of Russian scientific workers to keep in touch with scientific work and progress in the world also and for such interchange of young men of science and research students.

Several of the British visitors have surveyed very briefly their general impressions of Russian progress in the various branches of science, and elsewhere in this issue of *Nature* we are publishing some of these articles. From these it seems clear that Russian men of science and their Government desire such a two-way traffic. Prof. Andrade writes of the abiding impression made by the spirit of cordiality and co-operation in which the delegates were everywhere received. Prof. Watson refers to the real need for closer contact with workers in other countries, and especially of travel, and of the dependence of satisfactory work on such free association of workers in all lands. Prof. E. D. Adrian makes the same point even more emphatically in respect of physiology. Until the war-time restrictions on travel are removed, we shall not properly appreciate all that Russian physiologists are doing, and they will have no first-hand experience of our methods and ideas. We and they both need an exchange of students in addition to the exchange of journals.

Everyone is so aware of this, and the delegates were so cordially received, that it is hard to believe that the restrictions will remain, particularly in view of the speech of Kapitza on June 23, which showed that the U.S.S.R. recognizes the importance of international co-operation and that the Academy intends to promote international co-operation by these measures, all of which have been urged on the Government of the United States in Dr. Vannebar Bush's report. When Prof. Adrian concludes that the British delegates will only complain if they are not allowed to repay some of the kindness shown to them by their hosts, he is clearly expressing a common sentiment. It may be a further hopeful sign that there should since have been published the draft proposals for an educational and cultural organization of the United Nations, to be established, according to the preamble, in recognition that "co-operation in education and the furtherance of cultural interchange in the arts, the humanities and the sciences will promote the freedom, the dignity and the well being of all and thereby assist the attainment of understanding, confidence, security and peace among the peoples of the world"; and in dedication to the proposition "that the free and unrestricted education of the people of the world and the free and unrestricted exchange among them of ideas and knowledge are essential to the advancement of huma welfare and to the preservation of security and peace.

But for the effective promotion of scientific inte course across national frontiers, something more tha organization is required; and the point has bee uncomfortably emphasized in connexion with thi very visit to the Academy of Sciences of the U.S.S.R The appointment of scientific attachés might indee do something to increase the flexibility of organization, to promote more informal and intimate contact as well as to remove causes of misunderstanding Such a system may become imperative to the buildin up of the confidence essential for framing a system of co-operation in handling and harnessing to constructive purposes the new powers disclosed in th release of atomic energy; but so far, apart fron Great Britain's agricultural attaché in Washingto and Prof. E. Ashby's appointment to the Australia Legation in Moscow earlier this year, no practica steps have been taken to give effect to an idea whic has already been widely discussed among scientifi workers.

If the recommendations of Dr. Vannebar Bush' report are accepted, we may expect to see the Unite States also experiment with scientific attachés i certain embassies, and Dr. Bowman's Committee ha the U.S.S.R. specially in mind in making the suggestion. No system of scientific attachés, however can obviate the need for the handling of scientifi co-operation and communications with more understanding, not to say courtesy, by Governmen departments and officials generally.

The readiness with which scientific workers have accepted the restrictions on their freedom of communication does not mean that such restrictions should be imposed unreasonably or without regard to the common courtesies of civilized life.

It is on this ground that men of science in Britain have a right to protest firmly against the circumstances in which the exit permits of eight of their colleagues invited to attend the anniversary celebrations of the Academy of Sciences of the Soviet Union were cancelled at the last moment by the Government. We may leave the Foreign Office to deal with the discourtesy to the Soviet Government implied in such a cancellation; but however substantial may have been the reasons which decided the Government to withhold permission for these eight men to proceed to the U.S.S.R., we cannot reasonably be expected to believe that such a decision could not have been reached at a much earlier stage. The complete disregard of all personal considerations has undoubtedly roused strong resentment, and scientific workers owe it to themselves to protest emphatically against what appears to be a piece of bureaucratic incompetency or tyranny.

The right of the Government to impose restrictions on international scientific intercourse, at any rate in war-time, or to lay down conditions to which such intercourse must conform, is not challenged; though scientific men have a perfect right to consider for themselves whether it is worth proceeding with a particular foreign visit under particular conditions. Even with the improvement of communications through air transport, however, a visit to such a country as the U.S.S.R. is not to be undertaken without a certain amount of personal inconvenience. Responsible scientific men may have to obtain leave of absence and to arrange for deputies during their absence; private arrangements have to be made regarding homes or families; and in these days, in addition to passports and visas, there is usually inoculation against typhus or other diseases likely to be encountered, with all the physical discomfort or even incapacitation that is involved. No one complains if for some urgent and unexpected reason it is necessary to cancel at the last minute arrangements made in good faith, but common decency should forbid any one being put to the inconvenience involved in the preparations unless there is every reason to believe that he or she will make the journey.

Nor is it merely in regard to scientific workers leaving Britain that there are strong grounds for complaint of official slackness and discourtesy. The treatment of distinguished scientific visitors to Great Britain leaves a great deal to be desired. Both in entering and in leaving the country, such distinguished visitors, possibly invited by a scientific society of standing, may be obliged to spend the better part of a day awaiting their turn at government offices completing various formalities. There should be some mechanism whereby distinguished men of science entering or leaving Britain could be given the privileges accorded to those of ambassadorial status, for truly they are ambassadors of science. An intermediary is evidently required, able to keep in touch with learned societies on one hand and Government departments on the other. Such a body would be a centre to which those desiring to entertain foreign visitors would hand over all formalities; it might equally act for British men of science visiting foreign countries. Something on these lines is being done by the British Council, but more comprehensive action is required; the Council, however, if suitably strengthened, might be an appropriate body to undertake such activities.

Sir Henry Dale has pointed to some of the implications of the atomic bomb and the control of atomic energy for the full freedom of scientific intercourse; and the importance of full scientific intercourse across national frontiers, as already indicated, has never been more widely recognized. While the improvement of scientific communications is urgently required, and the relaxation so far as possible of the war-time controls over publication, it may still be necessary to retain some measure of Government control. Such restraint should be reasonable, however, and the minimum consistent with the national interests regarded from the broadest point of view. Scientific workers have a right to expect and to insist that Government departments to which the framing of the necessary regulations is entrusted are staffed with those competent to do their work with imagination and understanding of the real issues—constructively and not obstructively—and to administer and interpret them with common sense and courtesy.

METHOD IN METAPHYSICS

The Nature of Metaphysical Thinking

By Dorothy M. Emmet. Pp. xi+238. (London: Macmillan and Co., Ltd., 1945.) 10s. 6d. net.

MISS EMMET describes metaphysical statements as statements about the real which transcends experience. Her view in brief is as follows: There is a real world of which we are part and to which in our living we are responsive, but of the nature of which we have no direct experience. Nor have we any means of characterizing it as it is in itself, since in all our awareness, whether through sensing or through reasoning, what is displayed is rather our responses to it than its own nature. In this sense the real transcends experience.

But since we feel ourselves responsive to it, we can describe it indirectly in terms of our responses. We need not, however, confine ourselves to simple statements such as that 'the real is that to which we respond in such and such ways'. We want to tell a connected story about it, to make it out as having a structure which seems intelligible to us. Miss Emmet is concerned with the question of the ways by which we do this, what justification there is for doing it, and in what sense, if at all, the accounts we give in this way can be true.

The fundamental method on which she lays stress is that of analogy. This is used in science, in the building up of any theory. Some experienced arrangement which seems intelligible is taken as a model for the description of a situation the details of which cannot be experienced. Such a model is valuable not merely for predictions, but also as giving an intelligible co-ordination of various observed facts, and as a means toward the forming of more complex models in relation to wider situations; and while it cannot be taken as a literal representation of the situation as it is in itself, it can be taken as corresponding in some way to the situation, even though we cannot say directly how.

In religion, theology and metaphysics, analogies are used in the same way as in science. But there are certain fundamental differences. The former are concerned with what, following Prof. Stocks, Miss Emmet calls total assertions: assertions about the nature of the real considered as a whole, and therefore qualitative, whereas assertions in science are concerned with features from which quantitative relations can be derived. The basis of this difference is her view that some of our responses to the world are responses of our whole being to some feature of the world considered as an individual whole, while others are responses of part of ourselves to some partial feature of the world: somewhat as, for example, I may stand on tiptoe to help my tall friend to put on his overcoat (partial response to a partial feature), whereas my whole being goes out to him in admiration when he shows some special excellence of character (total response to a total feature).

I have no space to deal with Miss Emmet's interesting and careful account of analogies in religion and theology. A metaphysical system takes its rise in total responses. As a starting point, we can say that the world has such a nature as to rouse these responses in us. The next step is to seek for some further account of it which will enable us to link our various total assertions into an intelligible system. Analogy is fundamental here, as in science. Some type of situation is felt by a particular thinker to be of special importance within human experience, and also to provide a clue to that in the nature of the whole which calls out our total responses to it. Further than this, in principle, he cannot go, in his account of the whole. He can never say directly what it is in itself. His account remains analogical and symbolical.

Such an account of the real is valuable partly because of the way in which it enables us to co-ordinate our experiences in various fields. But it may be valuable in this way only for particular persons at a particular epoch; and this partly accounts for the variety of metaphysical systems. When a system has lost this value, it can still have a value of a different, though perhaps less exalted, kind. It brings out more clearly the significance of the system of relationships within experience which provided the original clue.

Miss Emmet admits that the present age is not favourable for system building. "The real problem is that our diverse worlds of thought do not make sense as a coherent unity." Even when the physical and the social sciences make a new synthesis possible "it may well be that . . . we shall have learnt that the old style synthesis in the grand manner is impossible". At the same time she feels that failure to reach some such co-ordination results for many people in a failure to achieve any sort of significant communication with their fellows. She suggests in her closing pages that our most pressing need is to get clear about the difficulties of communication. How can we get across the barriers which divide people whose types of experience are diverse? To answer this question we need more investigation into the nature and the potentialities of what she grandiloquently calls "the word". At the same time we should be alert to new "possibilities of responsive awareness", to be ready for a new master analogy.

Miss Emmet thus has quite modest expectations in regard to metaphysics, at least in our time, and for her modesty there should be nothing but approval. The doctrine in her book which needs most critical scrutiny is the view that some of our responses can be taken as responses to some qualitative feature of the world as a whole. She says that we can take them as such only by an act of faith, by which she means a decision which is different in kind from any decision based on reasoning or on considerations about probability.

But if so, assertions about the world based on these responses are pre-judgments which stand in need of justification. The kind of justification she offers is that of ~~coherence~~—success in giving a systematically connected account of the world, which appeals to us as intelligible, and which serves to clarify and to intensify those responses we took, on faith, to be responses to the world as a whole. I am sceptical about the value for knowledge of all this. I cannot work up any interest in the idea that we are responsive to features of the world as a whole; and the fact that there are many different accounts which claim to be coherent seems rather to indicate that the responses on which they are based are only partial. Very often "giving a coherent account" simply reduces to "telling a good story". A good story is itself capable of playing on people, and rousing in them responses which are quite easily interpreted as responses to the world, and which in this way increase the convincingness of the story: for this reason, I think, coherence is not a satisfactory test of truth in any field where responses of this indeterminate character form part of the material to be woven into the system. In scientific investigation, the important responses are those made by instruments; and while the interpretation of the response made by a scientific instrument depends on the general body of theory which is being developed by its aid, yet the response itself is independent of any theory. If the responses of the instruments were affected by the theories they supported, scientific workers would all be medicine men with inadequately controlled theories. Stories about the universe as a whole do not seem to be in any better case.

The book is an attractive one. Miss Emmet has a wide knowledge of theological and philosophical literature, often shows great delicacy of perception and has a fund of self-criticism which keeps her from thinking it a merit to get conclusions, whatever the evidence. I have only one complaint about her style She has a habit (which seems widespread nowadays of preferring abstract or generic nouns to concrete nouns. The subjects of her active verbs are rarely concrete nouns. Phrases such as "Conceptual activity orders and interprets . . .", "Faith confesses . . .", "The religious mind seeks . . .", "The religious symbol conveys . . .", "The word discloses . . ." are frequent in her pages. Abstract words have a place even in philosophical language; but in discussions of the kind dealt with in this book we cannot afford to flirt with plausible rotundities, which play on our emotions and put our critical faculties to sleep. The more concrete we can make our language, the better will be our chance of finding out how untrue are the things we say. In this lies our only hope, when we are trying to speak truly.

L. J. Russell.

THE POSTHUMOUS TESTIMONY OF AN ANTHROPOLOGIST

A Scientific Theory of Culture

And other Essays. By Bronislaw Malinowski. Pp. ix+228. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1944.) 18*s.* 6*d.* net.

BRONISLAW MALINOWSKI, born in Poland, died three years ago at the early age of fifty-eight. Besides carrying out detailed and exceptionally brilliant field-work in Melanesia and New Guinea and for shorter periods in Australia, East Africa and Mexico, as professor of anthropology in the University of London, and attracting to himself a large number of able students, he displayed throughout his life the keenest interest in developing the theoretical background of his subject. His well-known theory of culture, presented by him in this volume in its finally elaborated form, has been for many years before his anthropological colleagues and has met alike with acceptance and with severe criticism. It is couched in terms of 'functionalism'; and by 'function' he means "the satisfaction of human needs". Even 'basic' human needs (for example, those of hunger and sex) demand cultural satisfaction; and they become linked up with new, 'derived', cultural needs. Any analysis of culture, he says, "in which we attempt to define the relation between a cultural performance and a human need, basic or derived, may be termed functional" (pp. 38, 39).

Two-thirds of this book is occupied by the author's presentation of his "Scientific Theory of Culture". It is followed by two shorter essays, one entitled "The Functional Theory of Culture"—which he regards as "a mere sketch" (p. 175)—and the other, "Sir James George Frazer: a Biographical Appreciation" (tempered by some *de*preciation !), both of which help to clarify his position. All three essays travel far beyond their respective titles. But he regards the scientific study of culture as "the real meeting-ground of all branches of anthropology" (p. 4). Indeed the whole volume presents an invaluable critical examination of the past, present and future trends of the science of anthropology in each of its many aspects. It describes what appear to the author to be the uses and abuses of the various methods hitherto applied, and is thus a work which no student of modern anthropology or sociology can afford to ignore.

Malinowski's theory of culture is psychologically based on 'behaviourism', of a not extreme type. No doubt this attitude became strengthened when, towards the close of his life, he served as visiting professor at Yale University and came under the influence of the distinguished behaviourist, Dr. Clark L. Hull, who holds a chair there in psychology. Malinowski proclaims his sympathy with what he terms the latter's 'stimulus-and-response' school of psychology, and he stresses "the great importance which behaviourism promises to acquire as the basic psychology for the study of social and cultural processes" (p. 23), because it "allows us to describe facts which can be observed" (p. 71). He wisely warns us of the dangers of what he terms the "psychological method" of considering "what the primitive might have or ought to have thought or felt under certain conditions, and, how out of such a thought or feeling, a custom, belief or practice crystallized" (p. 19). Yet two facts are inescapable: that not every human action can be regarded as a sensori-motor function, and that in behaviourism the introspections of the conscious subject are only too apt to be replaced by the interpretations of the conscious observer.

Malinowski gives the name 'institution' to each unit of organization into which culture can be analysed; in his view the institutional structure of every culture must be recognized. "No element, 'trait', custom or idea is defined or can be defined except by placing it within its relevant and real institutional setting" (p. 54). He recognizes seven "general principles"—a rather heterogeneous medley listed by him as reproduction, territorial, physiological (due to age, sex, etc.), voluntary associations, occupational and professional, rank and status, comprehensive ("the integration by community of culture or by political power")—which bind human beings together into permanent groups. Under each of these so-called "general principles" he lists a large number of universal institutional types which he allocates to the "general principles" from which, he believes, they have been derived; for example, the family, kinship, marriage, co-operation within and outside the household, the sexual differentiation of labour, secret societies, occupational institutions, distinctions of class and caste, and institutions arising from the exercise of authority. Such a scheme, even if theoretically inadequate, will at all events, as he urges, prove helpful to the student and to the field-worker investigating an unknown area, and as a measure in comparative research.

The author's next task is to list under three vertical columns, respectively headed (in functional terms) "impulse", "act" and "satisfaction", eleven "permanent vital sequences" (for example, hunger, thirst, sex-appetite, somnolence, bladder-pressure, fatigue and fright) which he regards as "incorporated in all cultures", in accordance with his view that all cultures have essentially a physiological basis. He proceeds to show how the "act" and the "satisfaction" of these "vital sequences" are regulated, defined and thus modified by culture. Next, he sets forth the "basic needs" of human communities (for example, bodily comforts, health and safety), and he considers in respect of each of these needs the "cultural responses" which are derived from them and the "derived needs" to which under social conditions they have given rise. Finally, he analyses these "derived needs" or "cultural imperatives" under the four main lines of cultural response to them, which he defines as economics, social control, education and political organization.

Malinowski lays stress on the distinction that must be drawn between the tribe-State and the tribe-Nation, that is, between the tribe as a political organization and the tribe as a cultural unit. Whereas the "charter" of a tribe-State—its purpose as entertained by its members—"is that unwritten but never absent constitution of authority, power, rank and chieftainship" (pp. 165, 166), the charter of a tribe-Nation is to be "found in those traditions that deal with the origins of a given people" and describe "their cultural achievements in terms of heroic ancestral performance" (p. 165).

"Culture", Malinowski wisely concludes, with special reference to present-day conditions, "as a way of life, as a national type of pursuit, taste and interest, cannot be dictated, controlled or legislated. It ought to be given the best conditions for development, and cross-fertilization with outside influences, but left to maintain its own balance and its own development under conditions of full autonomy" (pp. 220, 221). Anthropological analysis "would reveal that nationhood is a much older and more fundamental principle in evolution than the political organization of a police system, a tribe-state, or an empire" (p. 217).

C. S. MYERS.

A NATURALIST OF THE HIGHLANDS

A Highland Year

By Seton Gordon. Pp. 152+23 plates. (London: Eyre and Spottiswoode (Publishers), Ltd., 1944.) 12*s*. 6*d*. net.

MR. SETON GORDON is one of the few men of education who have been content to live their life in the Highlands rather than earn what many would consider to be an easier and better living elsewhere. The result is that, being a life-long observer, he knows more about the natural history of a remote region than almost anyone else. He has preferred to diffuse his wide knowledge in the form of popular books rather than as systematic papers, a fact for which many general readers are undoubtedly thankful. We of a younger generation of workers may be sorry that he does not give us a compendium or source-book which he alone could write and which would preserve for us the great variety of knowledge which his sensitive, inquiring mind has gathered. Nevertheless, here is a book written graciously, one which in the opinion of the reviewer stands out as Seton Gordon's best.

The only plan the book can be said to follow is based on the title of "A Highland Year", the chapters being the months, beginning at October, which is a good choice. Within his months, Seton Gordon allows himself complete freedom of anecdote and description, jotting down in leisurely fashion an immense range of facts of natural history. Observers studying bird behaviour will find several points of interest: for example, a case of a black-throated diver moving her eggs from one islet to another in a hill loch during a heavy spate. This bird continued to sit on the eggs in their new place. A wagtail's nest in a quarry on the new Glencoe road was moved several yards by the navvies to a new site on the quarry floor, where they built a cairn round the nest to give it shade and protection. The birds continued to sit in the new place and reared their young, blasting, lorry-loading and hubbub notwithstanding. These occurrences are in such sharp distinction to that narrowly limited pattern which Howard with corn buntings and Kirkman with black-headed gulls have shown to be common in the perception of the nest site.

The influence of man on wild animal life in Scotland is described in many notes. Ptarmigan, for example, are extinct in the Forest of Harris, their last haunt in the Outer Isles. Rabbits increased to such an extent on the Slopes of Clisham, the highest hill (2,665 ft.), that someone put down ferrets. It would not have needed much actuarial knowledge to have contrasted the reproductive potentials and expectations of survival of these two species. Ptarmigan have gone; the rabbits remain. Less than a century ago, the pine marten was common in these treeless hills, but its influence on the ptarmigan was apparently much less harmful than that of the ferret.

Seton Gordon often speaks of the lobster fishery of the West Highland and Hebridean coasts: it has been prosecuted with intensity during the War, but as yet we know little or nothing of the cropping potential of this valuable wild-life resource. It is unfortunate that public opinion has not yet enforced what provident common sense dictates in the handling of these shellfish. Lobsters are still sent to Billingsgate alive with an estimated consequent loss of 25 per cent. Many lobster fishers still 'cut' their catch, that is, prevent these shellfish fighting in the crowded conditions of the box by severing the tendon of the main claws at the joint. This suffering could be eliminated by installation of 'quick-freeze' plants in the catching areas and transport costs would be reduced.

Seton Gordon the naturalist tends to overshadow the judge and talented player of the Highland bagpipe. He is an authority on *ceol mor*, the 'great music' of Gaeldom. The *piobaireachd* is a severely disciplined classical form comparable with the fugue, but a bigger thing altogether; yet the author of this book considers, with other pipers, that *piobaireachd* is dying. Is this because the bagpipe remains a solo instrument for its classical music, and times and places are few in modern life when this form can be appreciated? Perhaps we may yet see the *piobaireachd* orchestrated and brought to a wider field of music lovers. F. FRASER DARLING.

FOOD SCIENCE

The Chemistry and Technology of Food and Food Products

Prepared by a Group of Specialists under the Editorship of Dr. Morris B. Jacobs. Vol. 2. Pp. xx+890. (New York: Interscience Publishers, Inc., 1944.) 10.50 dollars.

HALF of this volume is concerned with unit operations and processes (describing generally the methods and equipment involved in the preparation of foods), food supervision by government agencies, sanitary and quality control, food machines, plant sanitation, control of insects and rodents, dehydration, food preservation by temperature control and by micro-organisms, canning, chemical preservatives and packaging. The other half deals with production and covers the milling of cereals, bread and bakery products, sugars, chocolate, fruit juices, milk and milk products, meats, oils and fats, beverages and industrial waters.

The book suffers from the weakness of being too comprehensive, and as a result many important aspects are dealt with inadequately. It is doubtful if the section on food supervision will interest the average food technologist, while the engineer interested in machines for food processing would probably gain more from a study of the elaborate catalogues produced by manufacturers. By contrast, the section on plant sanitation is so loaded with detail that the principles and remedies tend to be lost. The sections on insect and rodent control make interesting reading, but it is obvious that American work is behind our own on, say, the question of insecticidal dusts. Again, no mention is made of critical moisture contents in relation to insect spoilage.

The dehydration of foods is dealt with in masterly fashion but to anybody who has investigated or even eaten these products, it is no surprise to learn that the conditions of storage are vital to palatability. The authors also fight shy of the nutritional aspects of these foods, while no mention is made of compression as a method of saving space and packaging.

Food preservation by temperature control is written by Dr. Tressler, a noted authority on this subject. He has, however, too much ground to cover in twenty pages, and as a result he inevitably sounds dogmatic even on difficult and complicated points such as the meaning of and the desirable relative humidity for the storage of a particular foodstuff at a given temperature.

The sections on production are all first-class, as would be expected from the names at the head of them. When they are objective, however, they refer inevitably to American practice. Thus Dr. Urbain gives a lucid account of operations in the Chicago stockyards, Prof. Geddes makes no mention of wheat blending which is of such interest to many European countries, and also scarcely mentions rye, while discussing maize in some detail. On the other hand, there is a stimulating section on alcoholic beverages, which includes a short chapter on Scotch whisky.

This volume, like its predecessor, is largely an account of American laboratory and commercial experience on the properties and production of foods. It is, however, a welcome addition to the literature on food technology, and Dr. Jacobs is to be congratulated both on his courage and his achievement.

T. MORAN.

ACADEMY OF SCIENCES OF THE U.S.S.R.

220th ANNIVERSARY

UST over a month after the Red Army had captured Berlin, the Academy of Sciences celebrated its vo hundred and twentieth anniversary by in-ting scientific workers from all over the Soviet nion and from eighteen foreign countries to meet Moscow and Leningrad. It was a very generous esture from a nation which has suffered so severely om the War, and it is evidence of the importance hich the U.S.S.R. attaches to international contacts ı science. For two weeks some nine hundred scientific orkers were guests of the Soviet Union. All the plendour of Russian hospitality was given to them. here were lectures and demonstrations and excurions. Soviet laboratories were freely opened for ıspection. Most foreign delegates came away with ery generous gifts of reprints and books and pecimens: for example, the four foreign botanists ach received a set of the ten volumes already pubished of the Flora of the U.S.S.R.

There were British delegates from the United Kingdom, Canada, Australia and India. Among the ther foreign countries represented were the United States, France, Sweden, Poland, Hungary, Yugoslavia, China. The visitors included many very istinguished men: Adrian, Joliot-Curie, Langmuir, Szent-Györgyi, Svedberg, to name only a few.

The celebrations opened in the evening on June 15 with a reception by the president of the Academy, Prof. Komarov. On June 16 the first celebration meeting was held in the Bolshoi Theatre. There were speeches from Komarov, Bruevitch, Orbeli, Prianishnikov and Kapitza. After the meeting there was a banquet for more than fifteen hundred guests, which continued until the early hours of the morning, and gave the delegates an excellent opportunity to overcome any shyness they might have had. On June 17 the Academy organized visits to museums, etc., in Moscow, and in the evening there was a second formal meeting at which the veteran Zelinski spoke, and greetings to the Academy were read by Shapley (from the United States), Sir Robert Robinson (from the Royal Society), Maurice Caullery (Paris Academy of Sciences), and others.

June 18, 19 and 20 were occupied by sectional meetings, visits to laboratories, and special performances of the opera and ballet. Several informal meetings of specialists were held: one on biochemists attended by Parnas, Szent-Gyorgyi, Englehart, Adrian, Needham, and others; one on physical chemistry, addressed by Langmuir, Macbain, Hinshelwood and Svedberg; one on soil science, addressed by members of the Dokachaieff Institute (under Praslov), and by Ogg and Kellogg. Lysenko addressed a special meeting on his theory of variability in inheritance. The next two days were spent in excursions: a boat trip on the Volga canal and a trip to Tolstoi's home at Yasnaya Polyana.

On June 24 the delegates were privileged to see, in the Red Square, the impressive Victory Parade. The salute was taken by Marshal Stalin and Marshal Zhukov, and despite pouring rain the parade was followed by patriotic demonstrations from the citizens of Moscow. That night three special trains left Moscow to take the delegates to Leningrad.

Leningrad gave the delegates a delightful welcome. Many of them were presented with bunches of flowers at the station. The first engagement was a tour of the "Defence of Leningrad" museum, which gives a vivid idea of the terrible privations the people of Leningrad have recently suffered. In the evening there was a performance of "Swan Lake". The next two days were occupied by meetings, visits to laboratories, and excursions. There were visits to the ruined observatory at Pulkovo, to Joffe's physico-technical institute and his physico-agronomical institute (under the Lenin Academy of Agricultural Science), to the Botanical Institute and garden, to Orbeli's physiological institute, and to other places. At a formal session of the academy, Orbeli gave an account of the work of the Pavlov school of physiology, and Komarov was admitted to foreign membership of the Linnean Society of London by its representative at the celebrations, Prof. E. Ashby.

On June 27 the Leningrad Soviet entertained more than a thousand guests to a banquet in the magnificent Uritsky palace. On June 28 there was an excursion to Koltushi, the laboratory where Pavlov worked, and where work is being done on the genetics of behaviour in animals, birds and *Drosophila*, and on the evolution of function in animals.

The delegates returned to Moscow on June 29 and in the evening they attended a special concert. On June 30, the Soviet Government gave a banquet in the great St. George's Hall of the Kremlin. Marshal Stalin, President Kalinin, Mr. Molotov, Marshal Voroshilov, and other leaders of the U.S.S.R. were the hosts.

British men of science who attended the conference are surveying work in their own fields which they have seen. Its quantity and quality in some branches of science were very impressive. Even during the darkest days of the War, scientific research went on. Of course, much of the energy of the Academy was devoted to the solving of short-term problems connected with the War, and one of the keynotes of the celebrations was the gratitude of the Russian people for the contribution of Soviet scientific workers to victory.

For the foreign visitor the celebrations were a generous token of the intention of the U.S.S.R to promote international co-operation in science. Through the initiative of the Soviet Government, contacts between Soviet scientific men and their foreign colleagues, so seriously dislocated by the War, have now been repaired. The hope of every foreign delegate is that the good promise of these two weeks shall be fulfilled. Perhaps the most important occasion of the celebrations was Kapitza's speech on June 23. He pointed out that the U.S.S.R. recognizes the importance of international co-operation in science, and that the Academy intends to promote international co-operation by three measures: (1) enlarging and extending its publications of scientific work in foreign languages, and publishing monographs in Russian, English, or French; (2) arranging and taking part in international congresses; (3) exchanging scientific workers between the U.S.S.R. and foreign countries. If, as a result of these celebrations, foreign men of science can keep in touch with their Soviet colleagues, can meet them at congresses, and even work with them occasionally, then the celebrations will be much more than a delightful experience: they will be the first step on the road to stable international co-operation.

SCIENCE IN THE U.S.S.R.

PHYSIOLOGY

By Prof. E. D. ADRIAN, O.M., F.R.S.
University of Cambridge

IN the summer of 1935, physiologists from all over the world gathered in the U.S.S.R. to attend the international Congress held in Leningrad and Moscow. Though we knew that scientific men there were held in high esteem and that our president, the renowned Pavlov, had every privilege the State could grant, we were not at all prepared for the magnificence awaiting us and for the intense interest which the doings of the Congress seemed to arouse in everyone we met. Whatever our political colour, we had to conclude that in the U.S.S.R. scientific workers were genuinely regarded as estimable people to be encouraged at all costs.

Ten years later, the jubilee meeting of the Academy of Sciences of the U.S.S.R. has reinforced this impression. We have been dazzled as before by stately entertainment, but although the spirit of victory was in the air, the meetings of the Academy were not merely an overture to the military parade before the Kremlin. We celebrated the achievements of Russian science, past as well as present, in all its branches, in archæology, linguistics and exploration as well as in aeronautics and chemistry. Clearly science and learning still hold an exalted position in the U.S.S.R. and the title of 'academician' carries more weight there than in any other country in the world.

What has science done to deserve such esteem ? In the U.S.S.R., as elsewhere, it has played an essential part in the War, and the great development of the country would have been impossible without it. For the man in the street, the achievements of science may be measured by the 'metro' and the higher yield of agriculture ; but the man in the street seems to read text-books on physics or astronomy (to judge by their sales), and it is evident that the respect for science owes something at least to the particular philosophy on which the State is based. Guided by this philosophy, the State is willing to spend very large sums on research institutes of all kinds and to keep large numbers of men of science working on problems of the more academic type in spite of the War and the shortages it has caused.

This is certainly its policy in physiology. The War has naturally focused attention on the nature of surgical shock, on blood transfusion and resuscitation, etc., but work on such problems as the chemistry of muscle and the development of functions in the embryo has continued, under difficulties of course, but with no lack of interest and official encouragement. Near Leningrad, where one in three of the inhabitants died of starvation in the siege, the large experimental station built for Pavlov at Koltushi is already a hive of activity. It has modern equipment and houses more than fifty scientific workers and many more technicians engaged on the problems of the nervous system. In the city itself, the large Pavlov Institute of Physiology is in full swing. In Moscow, work has gone on continuously in the research institutes directed by Academicians Orbeli, Lina Stern and Englehart. Many of the scientific workers in these institutes are women, but by no means all, and many papers have been publishe during the war period, some concerned with war-time problems but the majority dealing with pure rathe than applied physiology.

How far has this large-scale encouragement of science been justified by results ? In physiology ther have been few outstanding advances in recent years in the U.S.S.R. or anywhere else. The result which justifies the policy has been the general raising o standards, in equipment, in training and in th quality of the work that is published. In 1935, a now, the senior physiologists were men of established reputation, pupils of Pavlov, Samojloff or Wedensky but the juniors had little experience of physiology outside their own laboratories and could scarcely avoid some restriction of outlook. The training is now much more thorough, the libraries are better and there is far less reliance on traditional methods. The papers which are published reflect this improvement. The specia features of Russian physiology remain. There is the same keen interest in the central nervous system and in the interaction of the different regulating processes of the body ; but in addition there is the tendency to explore new fields with new techniques which has been characteristic of physiology elsewhere. A good example of this has been the recent almost simultaneous appearance of work on the electric response of the human eye from Moscow, Stockholm and Cambridge.

In the years to come, the U.S.S.R. with its large numbers of trained physiologists will have an output of research in that subject exceeding anything in Europe. There is little to criticize in the organization for this research. Whether the policy of large institutes with a pre-arranged plan is as good for physiology as it is for agriculture does not matter very much, for if it does not work it will be altered, as recent educational policy has been altered. On paper, the director of an institute may seem to have an uncomfortably large number of scientific workers to look after, but in fact he can probably trust most of them to look after themselves. The director has considerable power over his staff. Yet in any country the junior who disproves his professor's conclusions may find his position difficult, and there is no reason to think that these difficulties would be increased by the particular organization of the research institutes in the U S.S.R. But the physiologists there have had one disability which, if it persists, will certainly check the rapid development of the science. In the past, only a few of them have been able to visit laboratories in other countries for study and research. During war-time, restrictions on movement are inevitable and we have all suffered from them. Until they are removed we shall not properly appreciate all that Russian physiologists are doing, and they will have no first-hand experience of our methods and ideas. We and they both need an exchange of students and professors in addition to the exchange of journals. But everyone is aware of this, and we have been so cordially received on our visit that it is hard to believe that the restrictions will remain. It is significant that the first international meeting of scientific workers has been held in the U.S.S.R. Those of us who had the good fortune to attend it cannot complain of any lack of co-operation. We shall only complain if we are not allowed to repay some of the kindness shown us by our hosts.

CONTEMPORARY PHYSICS

By Prof. E. N. da C. ANDRADE, F.R.S.
University College, London

T must, of course, be clearly understood that the following brief notes do not profess to mention, even by name, every important line of research in physics that is going on in the U.S.S.R.; they cannot even hope to mention everything of interest that I personally saw during our recent visit as guests of the Academy of Sciences. They must be taken, rather, as general impressions left by the varied activities of the laboratories in which we were so warmly welcomed by our Russian colleagues, who were anxious to let us see the progress that they were making in the world of research, but equally anxious that we should not miss any of the receptions or festivities so bountifully prepared.

The leader of Russian physics is Academician A. F. Joffe, vice-president of the Academy of Sciences, who first began in 1903, in conjunction with Röntgen, the work on crystals which, in one form or another, has always occupied his attention. His book on the physics of crystals is known to most English physicists. He is now sixty-seven, but in full vigour and actively controlling a great variety of research, as well as pursuing his own investigations—a comment on the British system of fixing sixty-five as the retiring age in most scientific posts. In the Physico-Technical Institute at Leningrad, which is under his immediate direction, work is mainly concentrated on three general subjects, namely, semi-conductors, intermolecular forces in polymers and nuclear problems. It must be understood that the Institute was transferred to Kazan during the siege of Leningrad and did not return until March this year: it says much for the vigour of the laboratory that work is already in full swing on the first two subjects named, and it is not surprising that the nuclear work is only just beginning. The spectral distribution of particles emitted by the nucleus is the general theme that is to be undertaken.

Work on semi-conductors has for many years been a favourite subject with Joffe, and arose naturally out of his interest in the real structure of crystals. The investigations have been much influenced by a theory of the rectifying effect put forward some years ago by Joffe and Frenkel; incidentally, Frenkel's theoretical work pervades many branches of present-day physics in the U.S.S.R., and I much regret that a change in our general plans interfered with an appointment for discussion which we had made. Semi-conductors can show what may be for brevity termed both electronic and ionic conductivity, or positive and negative conductivity. It has been demonstrated in Joffe's laboratory that the same substance, for example, lead sulphide or thallium sulphide, can be produced with either high or low conductivity and with either positive or negative conductivity, according to the amount and the nature of small admixtures of certain substances. Excess of sulphur gives positive conductivity, excess of metal, negative. Active work is proceeding on many lines, both on the fundamental physical properties of semi-conductors, which throw light on the mechanism of conduction in solids, and on their practical use for industrial rectifiers. This combination of pure and industrial research in the same institute is typical of the U.S.S.R. system. Closely connected with the work on semi-conductors is that on photocells. The thallium sulphide cell developed under Joffe gives up to 8 milliamp. per lumen. In many of his own researches Joffe enjoys the collaboration of the charming Madame Joffe, who acted as our hostess on more than one occasion.

Work on dielectrics is also proceeding. For example, the dielectric properties of hexafluoride of sulphur, which has an electrical strength two and a half times that of air, are under investigation.

As regards the work on polymers, much is being done in the way of cross-linking the molecules of cellulose by acting on the hydroxyl groups, a process somewhat analogous to the vulcanization of rubber. In this way the fibres can be made either elastic or brittle, and filter papers have been prepared which retain their strength in water.

All kinds of physical work in other laboratories is under Joffe's general direction. He has, for example, taken a leading part in organizing work on the measurement of soil temperature by an ingenious new method and on the measurement of the temperature of leaves, which has led to important practical results in agriculture.

Academician P. Kapitza (or Kapitsa, as his name is usually transliterated by the Russians) has a splendid modern Institute for Physical Problems, built in 1935–36. The most striking work proceeding here is, on the pure side, that on the superfluidity of helium II, discovered independently in 1937 by Kapitza in Moscow and by Allen and Misener in Cambridge, and, on the applied side, that on the liquefaction of air by Kapitza's turbine liquefier and on the preparation of liquid oxygen from the liquid air by a new type of apparatus for fractional distillation. Kapitza has recently been studying heat transfer in helium II in its relation to superfluidity and has found that the supposed abnormal heat conductivity is really a manifestation of its abnormally low viscosity. Connected with this is the existence of a counter current in the liquid. There are also two possible velocities of sound in helium II, the existence of a 'second sound' having been recently shown experimentally by Peshkov. These most curious properties of liquid helium have been explained in a remarkable theoretical paper by Landau. Work in this field is being actively continued. As regards the production of liquid oxygen on an industrial scale, the turbine liquefier, described just before the outbreak of the War, has the great advantage that it can be started up very rapidly and that it is much smaller and easier to maintain than the conventional machine. One machine is said to have run non-stop for four thousand hours. The methods of producing liquid oxygen developed in Kapitza's institute are being installed in factories all over the U.S.S.R.

There are various special institutes in which physics enters largely, although not exclusively, into the work. The Optical Institute is probably the largest, employing in all about five thousand workers; an account of one of the most interesting developments there, Maksutov's meniscus telescope, was given in *Nature* of June 30, p. 798. The Institute for Theoretical Geophysics deals with geoprospecting by electrical, seismic and magnetic methods and by a new thermal method; with atmospheric electricity and the transparency of the atmosphere; with ionospheric phenomena; and with the light of the night sky, on which Khvostikov has worked extensively. Some of the work in Academician Semenov's Institute of Chemical Physics, housed in a converted palace, is of a very physical nature, as, for example, a special method of measuring the abnormal viscosity which certain liquids have in layers immediately adjacent to a solid boundary: this method consists in blowing off the liquid with a controlled current of air and measuring the dimensions of the resulting wedge-shaped film by interference methods.

Academician Sergei Vavilov, director of the Lebedev Physics Institute, who is in charge of research at the Optical Institute, is keenly interested in the history of physics: he published a Life of Newton in 1943, in connexion with the tercentenary celebrations of Newton's birth, and edited a collection of papers on various aspects of Newton's work, to which he contributed a chapter on aspects of Newton's optical work. He also contributed a study of Galileo's work on optics to a recently published Russian work on Galileo. He tells me that he is now engaged on a complete Russian translation of Newton's "Lectiones Opticæ": the English translation which appeared in 1728 is of the first part only.

Reference must be made to the work of Rehbinder on the effect of surface-active substances for facilitating the working of metals, and particularly to some very interesting recent work on the effect of surface-active films in decreasing the resistance to mechanical flow of single crystals of metals. These films send up the electrical resistance appreciably, indicating that they penetrate deep into interstices in the metal.

If it does nothing else, this brief account may give some idea of the variety of the work in pure and applied physics that is proceeding with vigour in the U.S.S.R. It cannot, however, convey the spirit of cordiality and co-operation in which we were everywhere received, which has left a deep and abiding impression in our minds.

ARCHÆOLOGY AND ANTHROPOLOGY

By Prof. V. GORDON CHILDE

University of Edinburgh

ARCHÆOLOGY and anthropology are classed as sciences in the U.S.S.R. and with other social sciences stand under the ægis of Akademiya Nauk as much as the natural sciences. Hence during the War, archæologists and anthropologists have been 'reserved' like geologists or physicists. However, several very promising men of the younger generation, notably E. Krichevskiў, perished during the siege of Leningrad, and the gaps left by such casualties will take time to fill. At the same time, archæological research naturally suffered worse dislocation since 1941 than that in sciences more directly related to the war effort.

Museum collections had inevitably to be packed up. But in Moscow the State Historical Museum is already re-installed fully and open to the public; in the University of Moscow, despite considerable damage sustained by the building, the collections of the Anthropological Institute are actively in course of reinstatement, and I was able to handle the skull of the Neanderthal boy from Teshik Tash in Uzbekistan. In Leningrad the treasures of the Hermitage were not due to come back from hiding places in the Urals until August; in the Ethnographic Museum of the Academy an impressive exhibition illustrated by choice specimens, hastily unpacked and specially arranged by the staff, anthropometric, archæological and ethnographic work of the last ten years. Terrible damage, on the other hand, has been done to the famous collections in Kiev and in many local museums in the Ukraine and the Caucasus, where much unpublished material has been destroyed or dispersed by the invaders. A fine Hellenistic sarcophagus from the Taman Peninsula, abandoned by the Nazis, has just been restored in Moscow from the fragments to which the enemy had deliberately reduced it.

Field-work and the study of the collected materials were never entirely suspended during the War. The exhibition in Leningrad and a special session of the Institute for the History of Material Culture (IIMK held in Moscow introduced the Academy's guests to the results of operations so recent that no published accounts have reached western Europe. In Transcaucasia, Zamiatnin's surveys of Abkhasia, initiated in 1934, have brought to light the first undoubted Acheulean hand-axes from the territories of the Union as well as flake industries of Clactonian and Mousterian types, all illustrated at Leningrad. Tolstov described before the Institute the main results of the expedition under his direction in the ancient Khorasmia (the lower Oxus valley). The earliest settlements discovered belong to hunter fishers whose ceramic remains show analogies with the chalcolithic cultures of western Siberia and the Russian steppes. To the later Bronze Age belong some very schematic rock-engravings, while during the first millennium B.C. an advanced urban civilization, based on irrigation, developed. From the fourth century A.D. cities began to give place to isolated castles and fortified manors. At the same session Passek described her first explorations at Vladimirovka in the Bug basin, a large village of the 'Painted Pottery Culture' often called Tripolyan—excavations abruptly terminated by the Nazi invasion in 1941. Her survey has revealed there the existence of half-subterranean dwellings (*zemlianki*) as well as no less than five rings of *ploshchadki*. The 'areas' of burnt clay designated by the latter term turn out to be the floors of rectangular houses, which have been baked by fires specially kindled upon them and on which are found clay ovens, ritual pedestals, querns and groups of vases. These observations confirm and supplement the conclusions drawn from the excavations at Kolomishchina on the middle Dnieper, published with full documentation (in Ukrainian with French and Russian summaries) in *Tripil's'ka Kul'tura* (Kiev, 1941).

In physical anthropology the outstanding exhibits in Leningrad were the reconstructions from the skeletal material of faces and busts ranging from the Neanderthaler of Teshik-Tash to historical personages like Timur and Yaroslav Mudryў, executed by the sculptor anthropologist, Gerasimov, and exhibited with a convincing explanation of his methods. At the same time an anthropometric study is in progress on the abundant skeletal remains from the Fatyanovo cemetery of Balonovo near Kazan, while Debetz is in eastern Siberia continuing his anthropometric survey. Similarly Okladnikov, being again in Yakutia, could give no account of his interesting archæological and ethnographic discoveries along the Lena. For the same reason, we must await publication to hear of Grakova's latest finds in Fatyanovo cemeteries and her geographical and chronological classification of Fatyanovo relics, which is already prepared for publication.

Publication of archæological and anthropological periodicals in Moscow and Leningrad has been suspended during the War, but not in the Transcaucasian republics—the Georgian branch of the Academy, for example, published Kuftin's "Earliest Roots of Georgian Culture in the Caucasus in the Light of Archæology" (using also philological evidence and that from early MSS. miniatures) in 1944. Moreover, the complete editions of two numbers of *Materialy i Issledovaniya* were annihilated by enemy action in Leningrad. Now No. 12 of *Kratkie Soobshchennie* has already been issued and new volumes of *Sovietskaya Arkheologiya* and similar publications are going to press. At the same time, even during war years, excellent works of popularization were published by the Academy, such as histories of the ancient world and of the Middle Ages, edited respectively by Struve and Kosminsky and both designed for middle schools. An exhibition of all its publications in the domain of social sciences was organized in the Academy's library and profoundly impressed Western visitors.

VERTEBRATE PALÆONTOLOGY

By Prof. D. M. S. WATSON, F.R.S.
University College, London

THE study of fossil vertebrates in the U.S.S.R. is concentrated in the Institute of Palæontology of the Academy of Sciences in Moscow, but two men who hold posts in Leningrad are doing important work in association with the Institute.

Fossil fish of many ages are found in the Union, often most beautifully preserved and of great interest. Asiatic Russia has produced a Lower Old Red Sandstone fauna, the Leningrad district a series of faunas from the top of the Middle Devonian upward, which are generally represented by perfectly preserved though fragmentary remains, and are of great interest because they are comparable with those of the Upper Old Red Sandstone of Scotland, the Rhineland, North America, and the Arctic regions. Carboniferous, Permian and Jurassic fish are known from Asia in perfect preservation; there are even late embryonic Palæoniscids!

The early Tetrapod faunas are represented by two horizons, known nowhere else in the world, which are more recent than the Artinskian Clear Fork of Texas, and older than the Tapinocephalus zone of South Africa. These faunas include Labyrinthodonts of structure intermediate between those of the Lower and Upper Permian, which are of much importance for our understanding of the evolution of the group, and they have yielded an extraordinary, extremely flattened animal which seems to be a Seymouriamorph. There are new Cotylosaurs of great interest, but the most striking specimens are those of mammal-like reptiles, belonging to the Deinocephalia, which bridge the structural gap between the Pelycosaurs, and specifically the Sphenacodontia, of Texas, and the South African Titanosuchids and Tapinocephaloids. These animals are perfectly preserved; indeed, the bones from one locality, where they occur in essentially quite unconsolidated sand, appear like fresh bones, the skulls being completely free of matrix inside and out, and complete skeletons are known. With them is found *Venjukovia*, a forerunner of the Dicynodons, perhaps an actual ancestor of *Endothiodon*, itself derived from a primitive Tapinocephaloid.

On the River Mesen there occurs a "M." Permian fauna of small animals which includes two Cotylosaurs essentially ancestral to *Procolophon*, and a remarkable reptile, *Mesenosaurus*, the rather Pelycosaur-like skull of which is in some ways most reminiscent of *Youngina*, and which may perhaps prove to be the ancestor of the whole group of Diapsids. The later Permian and Triassic Tetrapods include a varied assemblage of Labyrinthodonts and Seymouriamorphs of great interest, many Pareiasaurs and Dicynodonts, Gorgonopsians, Therocephalia and a most primitive Cynodont, all comparable with African animals.

The Tertiary rocks of the Union in Europe and Asia have already yielded mammalian faunas of many horizons from the Oligocene to to-day, and are being actively explored. Indeed, the Museum of the Institute has already mounted a splendid skeleton of a Lower Meiocene long-jawed Mastodon, perhaps the best in the world. They have half a dozen mounted skeletons of fossil rhinoceroses, including that of the giant *Indricotherium*, and much other material of equal quality.

It is evident that the collecting expeditions have been most ably carried out, the materials must have been properly bandaged, the preparation is perfect, and the Institute has an excellent artist and photographer.

Vertebrate palæontology, like palæontology in general, is essentially an international science; conclusions about phylogeny can only be drawn with any satisfaction after a study of the whole materials in the world—and the U.S.S.R. includes a very large part of the world. Lying as it does over a great continuous land mass between North America, India, Europe, and, though it does not directly meet that continent, also Africa, it may be expected to form the link between these regions of the earth and thus provide the solution of many problems of correlation of terrigenous deposits of all ages throughout the globe.

The palæontologists in the U.S.S.R. know more than a hundred entirely new localities which yield vertebrate fossils and are making arrangements for their exploration. There is, to my mind, no doubt that in the immediate future the U.S.S.R. will become the great centre of activity of vertebrate palæontology, giving us new facts in abundance and solving many outstanding problems of phylogeny and of migration.

It was therefore most pleasing to me to meet my colleagues in Moscow and Leningrad, to spend some happy days in discussion with them, and to establish a friendship which will, I hope, continue for many years. The group is composed of most active, enthusiastic and able men and women, in whose hands I feel that the future of vertebrate palæontology may safely rest.

But a real need is that of closer contact with workers in other countries, and especially of travel. It is essential that every palæontologist should be familiar with his materials, and they are preserved in museums all over the world. The Soviet workers should be able to visit the British Museum and those in America and Europe as easily as we can, and I, and my colleagues in England and America, should be able to visit the U.S.S.R. and give to the magnificent collections which are accumulating there the study which they deserve. It is on such free association of workers in all lands that satisfactory work on fossil vertebrates ultimately depends.

MEDICINE

By Prof. ARNOLD SORSBY
Royal College of Surgeons of England

THE normal correctives of sensational reports on medical activities at any particular centre or country are close personal contacts and a free flow of publications. Both these are conspicuously lacking in our relations with Soviet medicine, and it is therefore inevitable that our knowledge of Soviet medicine is at all times inadequate, and at times grossly misinformed. This is unfortunate, for Soviet medicine has a significant organization and substantial achievements.

The organization of Soviet medicine is conditioned no less by the immense territory of the Soviet Union than by the assured place research has in the organization of society. The territorial expanse imposes a considerable amount of decentralization. This is apparent in the structure of the medical services as a whole, and in research in particular. The medical services, though conceived on a central plan, have an endless variety of administrative organs. Each of the autonomous republics controls its own services, which supplement those of the Union. Moreover, the municipalities, different industrial undertakings, collective farms, and many other labour organizations have services of their own, again supplementing those generally available. Soviet medicine is therefore a national medical service in its widest sense rather than a State medical service; its distinctive feature is its stress on preventive treatment.

The organization of research facilities is essentially parallel to those of the health services. Not all research institutes are under the control of the Commissariat of Health of the U.S.S.R. The newly established Academy of Medicine, the successor to the Gorky Institute of Experimental Medicine (Viem), controls a large number, and there are also institutes controlled by the governments of the autonomous republics. Furthermore, the medical schools and the universities play a significant part in medical research, so that there is no lack of research facilities or of variety of opportunity and service. Though there is intensive specialization, rigid departmentalization does not appear to be prominent; if anything, the opposite applies. This is apparent from such typical institutes in Moscow as those devoted to neurology, neuro-surgery, occupational diseases and ophthalmology. Each of these institutes consists of a large clinical unit balanced by well-equipped clinical and research laboratories. While these institutes employ many full-time laboratory research workers, they also have many others with both clinical and laboratory duties. Planned research, as it is understood in these institutes, consists of the co-ordinated activities of different workers approaching an agreed problem from their own special angle. The close contact that an institute and its planned work makes possible ensures that laboratory workers are fully acquainted with clinical needs, while the clinicians know the possibilities and limitations of the laboratories. Though working in a team, the individual worker does not lose his identity, as is obvious from the publications in the journals, which are not more frequently than elsewhere collective reports. While of necessity the bulk of the research in a clinical speciality is concentrated in the institutes exclusively devoted to it, all clinical institutes are broadly planned and have many special departments. Thus impressive work in ophthalmology was proceeding at the Institutes of Neurology, Neuro-Surgery and Occupational Diseases, and no doubt in other institutes too, in addition to the Institute of Ophthalmology. Some institutes are devoted exclusively to laboratory work in special fields, but these too do not appear to be narrowly conceived: at the Institute of Microbiology there was considerable work on pharmacology.

The team spirit and the organization of planned research probably ensure that in the Soviet Union more is known to research workers of unpublished work and its progress than is the rule elsewhere, and it is possible that publications as media for the dissemination of knowledge are relatively less important in the Soviet Union than they are in Britain. It is therefore all the more regrettable that there is so little personal contact between British workers and those of the Soviet Union.

Soviet medicine has grown rapidly, and in the course of its development has had to adapt itself to rapidly changing conditions. The training of medical men is as good an example as any of the empirical nature of much Soviet organization. No attempt is made to arrive at an ideal solution at any particular stage. When the need for numbers was urgent the training was not particularly exacting; and how urgent the need was is obvious from the fact that in 1913 there were less than 20,000 medical men in the Czarist Empire, whereas in the Soviet Union to-day there are about 150,000 and the number is still inadequate. As more physicians became available, the standard of training was persistently raised, and now has been fixed at a six years course. This is already operative in Moscow, and will become effective over the whole of the Union in the course of four years. This new level has rendered unnecessary such temporary makeshifts as specialization introduced at an early stage of the student's career. When the need was still pressing there was no general qualification in medicine; final-year students were trained for either public health activities, general practice, or children's diseases. While raising the standard of medical training, the Soviet authorities are still creating 'feldschers', relics of the old barber surgeons. They are given a practical training and are allotted much of the routine work of medicine, generally under supervision. In the course of time the 'feldscher' will no doubt disappear, but for the present his persistence is the price that has to be paid for the more intensive training of physicians.

It is the aim of Soviet educationists to produce 20,000 well-qualified medical men a year. The fifty-two medical schools at present available scarcely seem adequate for such numbers, but there is no shortage of candidates. Students for the medical schools are recruited from the secondary school population, and there are two systems of entrance. Those secondary school students who have a good record gain admission to the medical schools automatically; the remaining places are then filled by competitive examination from among the secondary school students whose record has not been so good. Stipends are paid throughout the student's career and they increase with each year of study. On qualification, students are expected to undertake three years service wherever the need is greatest; but many of those who have done well are expected to specialize immediately as clinicians or research workers. All who have given three years service are encouraged to "improve their qualifications", so that postgraduate study is a normal feature in the life of the Soviet physician. Soviet medicine has no fear about the standard and qualifications of its personnel.

A glance at Russian medical journals, and, still more, visits to hospitals and research institutes, show clearly that Soviet medicine is not 'practical' in the crude sense of the word. Though there is an ever-present need for personnel, and attention to the immense public health problems of the Soviet Union requires many routine workers, much of the work in the laboratories is of a highly abstract character. None the less, practical results are constantly sought. The immense flora and variety of soil conditions of the Soviet Union have been pressed into service. Systematic exploration of the pharmacological properties of the higher plants and soil bacteria is proceeding, while such institutes as that of balneology with its great variety of laboratories illustrates the use that Soviet physicians are making of the curative properties of springs and muds.

Although Russian workers have much to contribute to the rest of the world, they are borrowing freely from abroad, and, in some instances at any rate, have extensively developed work that was begun elsewhere and not carried to any conclusion. The production of lysozyme on a massive scale from a large variety of biological substances is an example. This achievement has been rather overshadowed by the coming of penicillin, but the Russian preparation of penicillin from *Penicillium crustosum* and their intensive exploration of the possibilities of producing synthetic penicillin illustrate once more that they not only borrow but also develop and improve on work from abroad. In the comity of civilized nations, Soviet medicine holds its place as an equal.

AGROCHEMISTRY

By Dr. E. M. CROWTHER
Rothamsted Experimental Station, Harpenden, Herts

RUSSIAN translations into English of the names of institutes and journals produce many uncouth phrases, such as "Chemisation of Socialist Agriculture" and others mentioned below, but occasionally they produce a word which we might well take over. Thus 'agrochemistry' describes fairly satisfactorily one of the halves into which our old science of agricultural chemistry is splitting up under the influence of increasing specialization. The subject covers crop nutrition and those branches of soil science concerned with soil fertility rather than soil formation and classification. The grand old man of Russian agrochemistry is D. N. Prianischnikow who, with a few other members of the Academy of Sciences, had received the highest Soviet award, Hero of Socialist Labour, a few days before our arrival. We were delighted to find him fitter and more lively in his eightieth year than when he last visited England in 1935 for the Third International Soil Congress at Oxford.

An outstanding feature of Russian agricultural science is the elaborate organization of team-work in a large number of institutes responsible to independent authorities. Considerable overlapping in programmes is not only allowed but also clearly encouraged. The necessary co-ordination is secured and a high standard of work maintained by requiring many research workers to divide their time between two or more institutes or colleges, and by giving a few overworked authorities responsibility for a broad group of problems in several institutes. Thus we saw one of Prianischnikow's teams at Dolgoprudnoye in the Gedroiz Institute of Fertilizers, Soil Management and Soil Science under the Lenin Academy of Agricultural Sciences, and another in the Department of Agrochemistry in the huge Timiriazev Academy of Agriculture, which has some sixty professors and 3,000 students. We also came across his pot-culture work in collaboration with the radioactivity section of the Institute for Geochemical Problems. Another example is afforded by the work of Prof. I. W. Tiurin on soil organic matter in the soil science departments of the University and the Forest Technical Academy at Leningrad and the Biochemistry Department of the Dokuchaiev Soil Institute at Moscow. Even Prof. Joffe, with all his other commitments in pure and applied physics, manages to find time to direct an admirable Institute of Physical Agronomy in Leningrad under the Lenin Academy of Agricultural Science. By means of his improved thermocouples, it was found that during August the night temperatures of potato leaves in the northern regions are often as much as 7° below those of the soil surface. This led to a new method of planting potatoes in wide high ridges across the direction of the prevailing wind, to transfer as much heat as possible from the soil to the leaves and so avoid late frost damage.

Prianischnikow has been checking his early work on nitrogen metabolism in plants and has confirmed that plants of all ages take up ammonium ions more rapidly than nitrate from dilute solutions of ammonium nitrate, though from unduly concentrated solutions nitrate may be taken up and ammonium excreted. In view of the acute shortage of nitrogenous fertilizers, which was manifest in all the crops we saw, Prianischnikow has great hopes of the benefits likely to accrue in the north from the rapid extension as a green manure crop of a frost-resistant Canadian strain of the blue garden lupin, *Lupinus polyphyllus*.

During the War, fertilizers could be spared only for a few industrial crops, such as cotton and irrigated sugar beet, but research on both the production and efficient use of fertilizers is well advanced. At Salikamsk there are larger reserves of potash than in Germany, and it is claimed that the U.S.S.R. now has larger reserves of phosphate than any other country. Until recently the only known deposits were low-grade rock phosphates and crystalline apatites, both unsuitable for making superphosphate. Brilliant work by Kazakov in the Institute for Fertilizers and Insecto-fungicides under the Commissariat for Heavy Industry has led to the discovery of vast deposits of high-grade rock phosphate in the Kara Tau region of Kazakstan. This discovery is also of considerable geological interest, for it was the outcome of a new theory of the formation of rock phosphate by precipitation from cold deep waters upwelling against a continental shelf.

Preparations are well advanced for using fertilizers on a vast scale. Thousands of field experiments have been conducted over a variety of crops, soils and regions, and individual collective farms are being mapped to show the best amounts and forms to use. Fertilizer consumption and crop yields should increase rapidly, especially in the leached soils of the centre and north, as soon as new factories and railways can be built.

The need for lime is still acute. About half the isolated limestone deposits are dolomitic, but recent work in the U.S.S.R., as in the United States and Great Britain, has shown that the old agricultural prejudice against this form is ill-founded. Indeed, it has been shown that some sensitive crops, such as serradella, lupins and potatoes, may safely receive full dressings of magnesian, though not of high-calcium, limestones.

Great importance is attached by the Mechanization Institute to a double plough in which a half-size plough precedes the usual digger plough. It is claimed that this buries turf and weeds more completely and avoids dead air spaces, and it was stated that no other type of plough is to be made.

Much work is being done on the difficult problem of analysing the production of tilth and the stability of soil aggregates. It will come as a shock to exponents of ley-farming in Britain to hear that several Russian workers hold that leys should not be grazed, at least for three years, lest trampling by stock should annul the granulating action of the grass roots.

(*To be continued*)

OBITUARIES

Major C. E. S. Phillips, O.B.E.

By the death of Charles Edmund Stanley Phillips on June 17, many will mourn the death of a very interesting personality.

Phillips was born on February 18, 1871, his father being Samuel E. Phillips, one of the founders of Johnson and Phillips, the firm which made some of the earliest electric marine cables. He was educated privately and studied, for a short time only, at the Central Technical College, South Kensington. It may be that it was owing to his rather unorthodox education that he was so versatile.

After the discovery of X-rays in 1895, Phillips devoted much time to the making of vacuum tubes and in studying their performance in his own laboratory at Shooters Hill. His friend, H. O. Mance (now Brigadier-General Sir Osborne Mance), who was working with him, has preserved some of Phillips's letters written to him early in 1896 describing his difficulties. In a letter dated May 4, 1896, Phillips says, "this afternoon I made a Röntgen tube myself but afterwards found the glass used was lead glass so gave it up as useless". In July of the same year he writes: "I've got an experimental vacuum tube nearly finished which takes to pieces and can be cleaned and exhausted. . . . There seems no doubt that the X-rays consist of rays having various different properties and are by no means homogeneous".

Phillips continued to experiment with vacuum tubes and published in 1901 a paper, which created a good deal of interest at the time, on the effects produced by a magnetic field upon the distribution of ions within a highly evacuated space (*Phil. Trans.*, A, **197**, 135; 1901). In 1908 he produced an electrical conducting glass (*Proc. Roy. Soc. Edin.*, 28, 627; 1908) from which the windows of electroscopes could be made. Unfortunately, the glass was never made commercially. In 1910 he delivered a discourse at the Royal Institution on the electrical and other properties of sand. In this he showed some striking and original experiments which might well be repeated.

Phillips was one of the founders of the Röntgen Society and read several papers before it. He served as its president in 1909. During 1914–17 he was in charge of the X-ray Department of the Royal Herbert Hospital, Woolwich, and during 1915–18 was physicist to the X-ray Committee of the War Office. Towards the end of 1915 he gave, at the 2nd London General Hospital, a course of lectures to the orderlies of X-ray departments on the physics of X-rays, Dr. Russell Reynolds dealing with the medical side of the subject. These courses of lectures may well be regarded as the initiation of the movement for training radiographers. Phillips was much concerned at the need of protection for those working with X-rays, and served as a member of the Inter-Services X-ray Advisory Committee from its inception until its dissolution in 1939. He was appointed brevet major (on reserve to the 5th Battalion Royal West Kent Regiment) in 1918 and received the O.B.E. for his services.

Phillips was one of the founders of the British Institute of Radiology and was its president during 1930–31. He was for some time lecturer on radiology at University College, London, and was also physicist to the Royal Cancer Hospital.

In 1909 Phillips suggested the use of a trace of radium with zinc sulphide for luminizing the dials of night-marching compasses, and the first model made by him is preserved in the Science Museum at South Kensington. It is unnecessary to stress the importance of this invention.

Phillips was one of the founder fellows of the Institute of Physics, and, if he was not the first to suggest the formation of the Institute, played the leading part in its formation in 1918. He was a member of the first Board and, except for one brief interval, served on it until his death; he had been treasurer since 1925. From 1929 until a few weeks before his death he was also honorary secretary of the Royal Institution.

Phillips was an excellent violinist and enjoyed playing on his Stradivari violin. In a discourse given before the Royal Institution in May 1935, he showed how he had tried to elucidate the secrets of the tone of the violins made by the old masters. He was also a good amateur artist; his portrait of Sir William Bragg now hangs on the walls of the Royal Institution. He gave great pleasure to many friends by his facility in depicting them in caricature. He was a delightful companion with a keen appreciation of a practical joke, especially if it had a scientific background. He was at his best at the dinners of the Physical Society Club, of which he was one of the founders.

In 1903 he married Winifred, the elder daughter of the late Mr. John Baines. R. S. Whipple.

Mr. R. W. F. Harrison and Mr. A. G. Hastings White, C.B.E.

The association of the main work of a lifetime with the affairs and traditions of an old foundation is, happily, not yet rare. With the recent deaths of Mr. Robert William Frederick Harrison (July 15) and Mr. Alfred George Hastings White (July 8), at the ripe ages of eighty-seven and eighty-six years, the Royal Society has lost links with a bygone generation. Both had made its interests the centre of their own and had become steeped in its traditions, though the manners of their service and the periods over which it was rendered differed widely.

Mr. Harrison was already a man of thirty-eight, with varied experience behind him, when he became assistant secretary; and when he retired, early in 1920, he had held the position for just under twenty-four years. He was born in the house of the London Library, St. James's Square, where his father was librarian. After schooling at Westminster he studied for and was called to the Bar, but never practised. At the age of twenty-four, in 1882, he became secretary to the Royal Society Committee arranging for observation of the transit of Venus. Then, after acting for a period as tutor to Lord Porchester, who became Earl of Carnarvon, he was secretary to the City and Guilds of London Institute and to the Art Union of London.

Fellows of the Royal Society still living will remember Harrison's entry there in 1896, when he succeeded the late Mr. Herbert Rix as the last assistant secretary to occupy the residential quarters designed for such use on the top floor of the Society's apartments. He did important services to the Society in a number of directions. The publication of the annual Year Book was due to him, he did essential work for the first three editions of the historical "Record of the Royal Society", and the attendance of the assistant secretary as minute-clerk at the Council meetings appears to have been an innovation due to him.

In those days of relative ease and leisure in the Society's affairs, Harrison, a man of rather striking personality, found time for a number of other interests. He was known as a violinist and a yachtsman. The article on the violin in the "Encyclopædia Britannica" (11th edition) was written by him, and, being a skilful carpenter, he converted a twenty-foot open boat into a yacht largely with his own hands, details of the structure, it is said, being actually fabricated in the Royal Society's rooms.

Harrison's knowledge of the Society's traditions grew with his devotion to its interests, and the devotion, as the years went by, not unnaturally took a rather possessive tinge in a man of his masterful temperament. Officers whose own experience had grown with his were easily tolerant of this, but those who had to face the changes and developments which came into view with the end of the War in 1919 doubted Harrison's adaptability to the new needs. He retired on pension, and the Council recorded the thanks due to him for his conspicuous zeal and devotion to the Society's interests; but he had not gone willingly, and he kept aloof for his remaining twenty-six years from the Society which he had so well served in his middle period.

Mr. White was a man of a very different style and temperament, whose services to the Royal Society extended over no less than seventy-three years in all. His father, Henry White, had graduated at Cambridge and qualified in medicine, but never practised, his interests being predominantly those of a scholar. Henry White had joined the staff of the Society in 1868 to edit its "Catalogue of Scientific Papers", and later undertook also the catalogue of all the books and papers in the Society's own library. By 1872 he needed help with these undertakings; and having perhaps lost faith in the value of a formal higher education, or lacking the means to provide it for his son, he took the boy Alfred at the age of thirteen from the North London Collegiate School and brought him as his assistant into the library of the Royal Society. It is of interest to remember that the Society was then still accommodated in old Burlington House, and did not move to its present quarters until a year later. It was in the Society's library, then, under his father's tuition and by dint of his own eager and unending diligence, that Alfred Hastings White obtained all that he ever had of secondary or higher education. He attained, in fact, to a fine though unusual scholarship, including a quite remarkable reader's command of languages, both ancient and modern, and a wide and detailed knowledge of the library in which he worked and which was to be for so many years under his care. Henry White died suddenly in the Society's meeting room in 1880, leaving his son, a young man of twenty-one, to be responsible alone for completing the catalogue of the library which was published in the following year.

In 1885 the Council appointed A. H. White "to assist the Secretaries in the work of publication and the work of the library pertaining to the office of Assistant Librarian", and this was his official position until he retired in 1930. In those forty-five years he had become the friend and helper of every fellow of the Society who used or took interest in the library, and of many whose papers he saw through the press. He had none of the system or technique of modern librarianship; but Nature, assisted, perhaps, by the manner of his training, had given him an extraordinary faculty of memory. References which he had once traced—shelf, volume and page—he seemed to retain indefinitely without written record and to produce at will. His unique knowledge of the library which he loved and cherished, his accumulating fund of varied information and bookish gossip, were almost too readily available to any fellow or visitor who showed interest. For many years he continued also to carry out the duty of formal editing and proof correction of all the Society's scientific publications, in addition to his library duties, and he retained this for the biological papers until he retired.

When he retired in 1930, after fifty-eight years of service, White was full of gratitude for the arrangement made, and anxious only for assurance that he would still have access to his beloved library. The Society gave him this with the appointment of 'consulting librarian', which he retained until his death, and only the failure of his eyesight restricted his enjoyment of it.

White is known to have contributed items to such publications as *Notes and Queries*, and sets of questions on general knowledge to the more popular Press, but he published little under his own name. The best-known publication attributable to him was his scholarly edition, which appeared in 1936, of William Stukeley's "Memoirs of Isaac Newton", the original manuscript of which had come into his possession. This treasure he later presented to the Society's library—a last token of a lifetime's affection.

To the memories of both these old friends, in such different ways its devoted servants, the Royal Society pays grateful tribute. H. H. DALE.

WE regret to announce the following deaths:

Mr. R. C. Porter, for thirty-seven years lecturer in the Department of Mechanical Engineering of the University of Birmingham, on July 28, aged seventy-three.

Mr. L. G. S. Reynolds, C.B., C.B.E., formerly Assistant Under-Secretary of State, Air Ministry, and since 1944 secretary to the Standing Commission on Museums and Galleries, on June 29.

Prof. Gustav Senn-Bernoulli, professor of botany in the University of Basel, on July 10, aged seventy,

NEWS and VIEWS

New President of the Academy of Sciences of the U.S.S.R.: Academician Sergei Vavilov

On July 17, Sergei Vavilov was elected as the new president of the Academy of Sciences of the U.S.S.R., in succession to Vladimir Komarov, the botanist. Vavilov, who is a comparatively young man—he graduated in 1914—is one of the leading physicists in the U.S.S.R.: he is director of the Lebedev Institute of Physics, named after his former teacher, and directs the research at the State Institute of Optics. His own work has been mainly in various branches of the science of light. On the more academic side he has carried out important researches in the field of luminescence and fluorescence, having not only put forward a theory of luminescence of solutions but also developed a method of analysis, based on luminescence, which is being widely used in the U.S.S.R. On the applied side he has done much to develop in the U.S.S.R. the fluorescent discharge lamps for domestic and factory lighting which are now becoming so popular in Great Britain and the United States. Vavilov has also carried out distinguished work on the influence of the quantum nature of light on vision and on physiological optics in general. Reference to his active interest in the history of science, and in particular to his studies on Newton, is made in the article by Prof. E. N. da C. Andrade on the recent visit of British men of science as guests of the Academy of Sciences, which appears on p. 223 of this issue. In the jubilee celebrations of the Academy, Vavilov played an active part, and his British colleagues who met him will be delighted to hear of the great honour that has accrued to him.

In addition to his distinguished and varied scientific experience, Vavilov is well acquainted with the tasks of general administration. He is a member of the Supreme Soviet of the Russian Federation, to which he was elected in 1938, and his services as a scientific worker and as a man of affairs have been recognized by the award of the Stalin Prize, the highest scientific distinction in the U.S.S.R., and the Order of the Red Banner of Labour and the Order of Lenin, which are very high distinctions. Vavilov is thus accustomed to solving both difficult scientific problems and wide problems of general organization and administration and is, in general, admirably fitted by temperament and training for the very important position that he is now to fill.

Chair of Botany at Leeds: Dr. Irene Manton

With the appointment of Dr. Irene Manton, at present lecturer in botany in the University of Manchester, to the chair of botany in Leeds, in succession to the late Prof. J. H. Priestley, the Leeds Department may be expected to maintain its record of scholarship and vigorous research activity. Although Dr. Manton's published work lies chiefly in the sphere of cytology, her extended studentship—Cambridge, with additional courses pursued in Switzerland and Spain—her subsequent tenure of postgraduate studentships (the Ethel Sargant and Yarrow) in Sweden, Germany, Cambridge and the Royal Botanic Garden, Kew, and further collecting journeys to France, the Mediterranean and Egypt, entitle her to be regarded as a botanist of wide general experience. This, together with her long teaching experience at Manchester (1930–45) and her skill as a cytologist will, without doubt, be seen to advantage as the Leeds Department develops under her guidance.

Dr. Manton's earlier work includes contributions to the cytological analysis of evolution. More recently, in collaboration with members of the staff of the National Institute for Medical Research, she has developed new technical methods whereby ultra-violet microscopy can be applied to problems of chromosome structure and in the resolution of nuclear problems, where the minute size of the objects under investigation has hitherto proved an insurmountable difficulty. This work, together with a comprehensive cytological survey of the Pteridophyta which is now approaching completion, will undoubtedly constitute a substantial contribution to botanical science.

Chair of Chemistry at University College, Dublin: Appointment of Dr. T. S. Wheeler

The Senate of the National University of Ireland has appointed Dr. T. S. Wheeler to the chair of chemistry in University College, Dublin, in succession to the late Prof. T. J. Nolan. Dr. Wheeler was educated at the Royal College of Science for Ireland, and served on the staff of the Royal Technical College, Glasgow (1920–21), and as a research chemist at the Royal Naval Cordite Factory, and at the Research Department, Woolwich. In 1928 he joined the staff of the Winnington Research Laboratories of Imperial Chemical Industries, Ltd., and was concerned with the investigation of a number of processes involving gas reactions at high temperatures and pressures. In 1931 he went to India as principal and professor of organic chemistry, Royal Institute of Science, Bombay. He took an active part in the scientific life of India, being for some time dean of the Faculty of Science of the University of Bombay, and a foundation fellow (sometime a vice-president) of the National Institute of Sciences of India. His research work in Bombay dealt mainly with the chemistry of chalkones and flavones. In 1938 Dr. Wheeler returned to Ireland as State chemist. He has been for the last seven years head of the State Laboratory, and has served on the Eire Emergency Research Bureau. Though primarily interested in organic chemistry, Dr. Wheeler has also published work on the theory of liquids. In this age of specialization Dr. Wheeler has had a varied career, typified by the fact that he is one of the few holding the three professional qualifications of fellowship of the Royal Institute of Chemistry and of the Institute of Physics and membership of the Institution of Chemical Engineers.

American Chemical Society, New York Section: Dr. Cornelia T. Snell

Dr. Cornelia T. Snell, of Foster D. Snell, Inc., consulting chemists and chemical engineers of Brooklyn, N.Y., has been appointed chairman of the New York Section of the American Chemical Society. Dr. Snell, who succeeds Dr. Ross A. Baker, professor of chemistry in the School of Business and Civic Administration of the College of the City of New York, is the first woman to preside over the New York Section, which with 4,148 members is the largest of the Society's 106 local sections. She has been serving as chairman-elect of the Section and would have succeeded to the chairmanship in 1946 upon the expiration of Dr. Baker's term of office. Dr. Baker resigned to serve as civilian educational specialist at a U.S. Army university study centre in Europe.

Dr. Snell, a native of Binghamton, N.Y., has been active as teacher, research worker, author and leader in chemistry. She received the degree of bachelor of science from Syracuse University in 1919, and for the next two years taught mathematics in a high-school. Her career in chemistry began after her marriage to Dr. Foster D. Snell in 1921. She took undergraduate courses at Barnard College, and pursued graduate studies at Columbia University, from which she received the M.A. degree in 1925 and the Ph.D. in 1930. Dr. Snell became research assistant in the pediatric department of the Fifth Avenue Hospital, and then spent a short period in the pathology department of the College of Physicians and Surgeons, eventually joining the organization headed by her husband. Dr. Snell was secretary of the New York Section of the American Chemical Society during 1937–44, and is chairman of the Women's Service Committee of the American Chemical Society. She is the author, with Foster D. Snell, of "Colorimetric Methods of Analysis", in two volumes; "Chemicals of Commerce" and "Chemistry Made Easy", in four volumes.

Men of Science in the Modern State

In his speech at the closing plenary session of the Commonwealth and Empire Conference on Radio for Civil Aviation on August 20, Lord Winster, Minister of Civil Aviation, said that among several myths which have been destroyed during the War has been that of the superiority of German men of science and of the degree of co-ordination which had been arrived at in Germany between science and industrial and war production. The course of the War showed not only that the United Nations have men of science second to none, but also that we have been far more successful in marrying their knowledge and their labours into the national war effort. Furthermore, it is now acknowledged that in future provision must be made in Britain for the training in its colleges and universities of far more scientific and technical workers than in the past, and that the pursuit of a scientific career must be made much more attractive in such matters as status and salary. These facts, Lord Winster said, are now recognized "and recognition will, I believe, be translated into action".

Lord Winster continued in a vein which will recall many an article in these columns. We have seen, he said, in the field of research what teamwork backed by unlimited funds can do. We have entered into a field in which the man of science will bring us knowledge which not merely enriches and facilitates the progress of the world but also determines the lines which progress shall take. If this is so we must alter our outlook upon the man of science; no longer can he be regarded as an interesting but unpractical individual. Even in the War of 1914–18 he did not achieve any very tangible recognition; in this War, thanks largely to Mr. Churchill, he has been coming into his own, and from now on he will be part of the warp and woof of the national life. In the future, the scientific worker by his discoveries will be determining the course the world will take. For this reason he must be brought out of the 'backroom' and brought in at the very highest level, not only for consultation about national affairs but also as regards the actual direction of those affairs.

Research in Animal Breeding and Genetics in Great Britain

As part of the survey which the Agricultural Research Council, in conjunction with the Agricultural Improvement Councils for England and Wales and Scotland, has been making of fields of research in which expansion is needed, special attention has been given to animal breeding and genetics as a subject of outstanding importance. After considering advice on developments in this field given by a special survey group, for which the American Government generously made available the services of Dr. R. T. Clark of Montana, and after consultation with the departments of agriculture, the Agricultural Research Council has appointed to its scientific staff Prof. R. G. White, professor of agriculture in the University College of North Wales, Bangor, and Dr. C. H. Waddington, of the Department of Zoology, University of Cambridge. Their first task will be to prepare a scheme for the creation of a national organization for research in animal breeding and genetics, covering the needs of Great Britain. Prof. White will be the director and Dr. Waddington will be chief geneticist.

It will be necessary for Prof. White and Dr. Waddington to investigate the systems adopted in other countries for the development of research in this field, so that a complete scheme cannot be ready for some time, though certain investigations of a statistical and fundamental character can be started in the near future. It cannot, of course, be indicated at present what centre or centres will be chosen for the development of research. The Council is, however, anxious that in any new developments full advantage should be taken of the experience of the Institute of Animal Genetics at the University of Edinburgh, which for so long has contributed to knowledge of these subjects and has been the centre of postgraduate training for workers from many countries. Similarly, it is the Council's intention, by close co-operation with practical breeders and the representatives of the agricultural industry throughout Great Britain, as well as with Milk Marketing Boards and other interested organizations, that arrangements shall be made whereby records are kept in such a form as to give the greatest measure of assistance to research workers in the new organization, and to be of real value in guiding the improvement of livestock. Research on such slow-breeding animals as farm stock must necessarily be lengthy, and results which can be applied with confidence in breeding practice cannot, therefore, be expected to emerge quickly.

International Co-operation in Social and Economic Fields

A pamphlet, "The New I.L.O", issued by the British Association for Labour Legislation, with an introduction by Barbara Ward, considers the position of the International Labour Organisation in relation to the Economic and Social Council of the Dumbarton Oaks plan, with the object of stimulating discussion on the planning of international co-operation in social and economic matters. Reviewing the past experience of the International Labour Organisation, the pamphlet is critical of the tripartite structure and questions the value of representation of employers except on the managerial or technical basis. A government should be the representative of the community as a whole, but governments should admit the workers also to the discussion of economic as well as of social problems, primarily to provide technical and constructive advice. In view of the clash and overlapping between general economic and social questions, the pamphlet appears to be dubious as to the continued existence of the International Labour Organisation as an entity, though this is not made clear. It is suggested, however, that the whole of the positive functions of the Economic and Social Council of the Dumbarton Oaks plan for constructing peace, as distinct from preventing war, should be discharged by bodies corresponding to those set up in 1918—an assembly, or conference, a council or governing body, and a secretariat or office, with committees to provide technical advice as required. The council would include representatives of the workers as well as governments and would take the place of the governing body of the International Labour Organisation. Its functions would include determining the agenda of the assembly, which itself would not be limited to government representatives. The secretariat would be divided into departments dealing, for example, with conditions of labour, with economic problems, with health and housing, with dependent territories and so forth, but with close inter-departmental relations. This plan would telescope the constructive functions of the old League of Nations secretariat and those of the International Labour Office, while employers or managers would find their place along with other professional men in the special committees created to advise on technical and practical issues. Although the Dumbarton Oaks plan is now, of course, submerged in the United Nations Charter, this pamphlet provides useful material for careful consideration.

Religion and Science

The conventional "conflict between religion and science" has concerned itself with questions which are not of themselves fundamental, and which are consequently incapable, as they stand, of any solution, as their perpetual recurrence indicates. The truth is, in Prof. H. Dingle's view, "that most of us have two different, and largely incompatible, attitudes towards what is essentially a homogeneous body of experience, and that we are, in the main, unconscious of this" ("Science and Religion." Modern Pamphlets on Religion, Life and Thought, No. 5. Union of Modern Free Churchmen, 92 Blake Road, London, N.11. 6*d*.). Both scientific and religious interpretations, in spite of their divergence from one another, are "attempts to interpret experience in rational terms". Their difference lies in their being concerned, in the main, with different kinds of experience, so that the interpretations which in either case seem most suitable are different. The scientific descriptions of the world are most appropriate for the particular limited fields of experience with which the respective sciences deal. The religious descriptions are those most appropriate for the different but also limited fields of experience with which religions deal. As knowledge grows, it may be expected that the two descriptions "will develop and ultimately coalesce into a single description capable of expressing all experience"; though we need not expect this ultimate description "to be identical with, or even greatly to resemble, any of the descriptions we can at present give"; and we shall therefore regard without concern any incompatibility between religious and scientific thought to-day. For we must recognize that the time has not yet come when we can construct a single comprehensive world-picture that will interpret all experience. We must be content with partial pictures, each limited to the experiences which provide its justification.

The Night Sky in September

New moon occurs on Sept. 6d. 13h. 43m. U.T. and full moon on Sept. 21d. 20h. 46m. The following conjunctions with the moon take place: Sept. 2d. 11h., Saturn 1° S.; Sept. 3d. 11h., Venus 3° S.; Sept. 4d. 22h., Mercury 4° S.; Sept. 8d. 00h., Jupiter 4° S.; Sept. 29d. 00h., Mars 0·2° S.; Sept. 29d. 20h., Saturn 2° S. In addition to these conjunctions with the moon, the following conjunctions take place: Sept. 9d. 12h., Mercury in conjunction with Regulus, Mercury 0·3° N.; Sept. 23d. 19h., Venus in conjunction with Regulus, Venus 0·4° N. Occultation of μ Gem (*D*). takes place on Sept. 1d. 3h. 39·2m., and of 147 B Aries (*R*) on Sept. 25d. 3h. 10·4m. On Sept. 29 there is a grazing occultation of 44 Gem. Mercury can be seen in the morning hours, rising at 3h. 51m., 4h. 13m. and 5h. 47m. at the beginning, middle and end of the month, respectively. The planet is at its greatest westerly elongation on Sept. 6. Venus can be seen in the morning hours, rising at 1h. 51m., 2h. 28m. and 3h. 07m. at the beginning, middle and end of the month respectively. Mars rises at 22h. 42m. on Sept. 1 and at 22h. 10m. on Sept. 30. Jupiter is unfavourably placed for observation. Saturn rises at 0h. 52m. at the beginning and at 23h. 12m. at the end of the month. Autumn equinox commences on Sept. 23d. 10h.

Announcements

A Conference on "Friedel-Crafts Catalysts and Polymerization" has been arranged at the Department of Chemistry, University of Manchester, to be held on September 15. Those taking part include Prof. M. Polanyi (Manchester), Dr. P. H. Sykes (I.C.I. Billingham), Prof. H. W. Melville (Aberdeen) and Prof. M. G. Evans (Leeds). Notification of attendance should reach Prof. Polanyi by September 1.

The annual conference of the Association of Special Libraries and Information Bureaux will be held at the Portland Hall, London, W.C.1, during September 15–16. The opening address will be delivered by Prof. J. D. Bernal, who will speak on the information service as an essential factor in the progress of science; there will also be a symposium on "Links with the U.S.A." and a discussion on the effects on education, research and cultural relations of the shortage of books. Application forms can be obtained from the office of the Association, 52 Bloomsbury Street, London, W.C.1.

The National Institute of Agricultural Engineering intends to recommence publication of the *Agricultural Engineering Record*, as a quarterly journal dealing with developments in the mechanization of agriculture. Publication was begun in 1940, but ceased after the first number because of war-time difficulties. The *Record* will contain accounts of the research and development work carried out at the Institute; and it is hoped that other workers in this field will also contribute to its pages. A new feature will be the inclusion of summaries of test reports issued by the Institute, when these have a general interest. The first number will appear in September, and thereafter on January 1, April 1, July 1 and October 1 each year (1*s*. per copy, or 4*s*. 4*d*. per year, post paid; subscriptions to the Secretary, National Institution of Agricultural Engineering, Askham Bryan, York; or to H.M. Stationery Office, York House, Kingsway, W.C.2).

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Further Observations on the 'Incomplete' or 'Blocking' *Rh* Antibody

WE would like to record a few more observations n the 'incomplete' or 'blocking' *Rh* antibody recently ound in human serum[1,2]. 'Incomplete' antibody iffered from other *Rh* antibodies in that it failed to gglutinate red cells carrying the equivalent antigen. did, however, block this antigen, so that subequent exposure to the homologous 'complete' or gglutinating antibody failed to result in the agglutnation of the treated cells. The antigen involved is hat called *D* in Fisher's notation[1]; other *Rh* antigens nd the antigens *A*,*B*, *M*,*N* and *P* are not blocked y this antibody.

Since the earlier communication, it has been found hat the 'incomplete' antibody is more thermostable han the 'complete' agglutinin. Heat just insufficient o cause coagulation of a serum (65°–70° C. for 5–10 minutes) will destroy all detectable *Rh* agglutinin but eave the 'incomplete' antibody apparently unchanged n quality or quantity. Heating a serum containing only *Rh* agglutinins has not so far produced 'incomlete' antibody. This greater thermostability of ncomplete' antibody compared with agglutinin has also been reported by Diamond and Abelson[3].

An early observation that, when antigen was added o a mixture of 'complete' and 'incomplete' antibody, he latter was absorbed preferentially shows that the incomplete' antibody is the more strongly adsorbed of the two. It was found that the 'incomplete' antibody would not pass through a collodion ultrailter, of a type used for osmotic pressure measurements and known to be impermeable to proteins of molecular weight 30,000 if not less. The filter was a semi-permeable membrane prepared from a solution of collodion in equal volumes of ether and alcohol, by Mr. H. Gutfreund of the Biochemistry Department, Cambridge, after the method of Adair[4]. Two thirds the volume of the serum was filtered using a pressure of one atmosphere. The ultra-filtrate contained no 'incomplete' antibody, which was still present in the ultra-residue. Thus it would seem likely that the incomplete antibody is of a protein nature.

We thought we might get some further information about the 'incomplete' antibody by noting the change n surface charge of red blood cells after being exposed to serum containing this antibody. The measurements were made using a cylindrical microelectrophoresis cell.

The suspending fluid for the blood cells was the standard saline phosphate solution used by Furchgott and Ponder[5], in their electrophoretic studies on human red cells. This solution was made up of nine parts of a 1 per cent solution of sodium chloride ('Analar'), and one part $M/15$ phosphate buffer at pH 7·38. This gave a solution having a final pH of 7·24 at 18° C., an ionic strength of 0·172, and a specific resistance of 70·13 ohms at 18° C. The readings were taken at room temperature (17–18·5° C.) at the 'stationary level' of the micro-electrophoretic cell. The specific resistance of the solution over this temperature range had been previously determined. The red blood cells used were of the genotype Rh_2rh, having the *Rh* antigenic structure $\frac{cDE}{cde}$ (Fisher[1]). These were obtained just before use by ear prick, suspended in saline and washed three times. Saline was then added to give a 0·5 per cent suspension. 0·4 c.c. quantities of this suspension were then treated as follows: (1) no further treatment; (2) 0·4 c.c. saline added; (3) 0·4 c.c. added of human serum (group *AB*), which contained no demonstrable *iso*-agglutinins of any kind; (4) 0·4 c.c. added of human serum (of the type now called by Wiener anti-*Rh'*) containing the incomplete antibody corresponding to the *D* antigen, but containing no agglutinin for Rh_2rh cells. (On removal of the 'incomplete' antibody from this serum, the absence of any masked corresponding agglutinin could be disclosed); (5) 0·4 c.c. added of human anti-*Rh* serum, of the type called anti-Rh_0, which contained only the agglutinin corresponding to the antigen *D*. All the sera had been previously heated to 56° C. for half an hour. Tubes 2–5 were incubated for half an hour at 37° C. The tubes were then centrifuged and the supernatant fluid replaced by an equal volume of saline. On resuspension, agglutination was present only in tube 5. The cells were then washed twice with saline and resuspended in the standard saline phosphate solution to give a 0·01 per cent suspension.

The electrophoretic migration of these five suspensions was then measured using a current of 3 milliamp., which gave a field strength of 5·85 volts/cm.

The cells were found to have the following mobilities (towards the anode):

(1) $0{\cdot}91_4$ μ/sec./volt/cm. (cells untreated).
(2) $0{\cdot}91_4$,, ,, (cells treated with saline).
(3) $0{\cdot}90_5$,, ,, (cells treated with 'inert' human serum).
(4) $0{\cdot}85_0$,, ,, (cells treated with 'incomplete' antibody).
(5) $0{\cdot}85_1$,, ,, (cells treated with agglutinin).

These results are only qualitative as they are the effect produced by the undiluted sera, and are not based on any definite sensitizing dose, which in the case of the 'incomplete' antibody is difficult to express. However, it would seem justifiable to conclude that there would have been ample sensitizing substances, in both the undiluted sera, to saturate all the homologous receptors on the blood cells: for the agglutinating serum had a titre of 1/128, and the serum containing the 'incomplete' antibody, in a dilution of 1/8, was capable of blocking the action of a strong agglutinating serum.

The interesting fact was that the effect on the charge of the red blood cells produced by the serum containing the 'incomplete' antibody was of the same order as that produced on the charge of the cells by the serum containing the 'complete' agglutinin. Also the cells sensitized with the agglutinin and the cells 'sensitized' with the 'incomplete' antibody had exactly the same charge; yet the former agglutinated and the latter did not. This shows definitely that the surface charge is not the one and only factor causing the actual agglutination (second stage).

The above experiments seem to show that the 'incomplete' antibody is probably of a protein nature, although remarkably thermostable. It appears to act in the same way as a true agglutinin, sensitizing the cell; but differing in that it lacks something in its structure which is essential for the agglutination of the sensitized cells.

We should especially like to express our sincere thanks to Dr. A. E. Alexander, of the Colloid Science Department, Cambridge, for his continued help and

advice in the microelectrophoretic studies recorded in this paper.

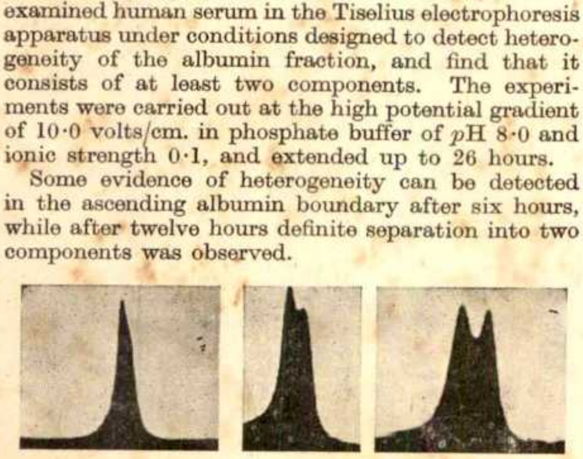
Heterogeneity of Human Serum Albumin

THE existence of more than one serum albumin in the horse has been demonstrated by chemical fractionation by several workers. We have now examined human serum in the Tiselius electrophoresis apparatus under conditions designed to detect heterogeneity of the albumin fraction, and find that it consists of at least two components. The experiments were carried out at the high potential gradient of 10·0 volts/cm. in phosphate buffer of pH 8·0 and ionic strength 0·1, and extended up to 26 hours.

Some evidence of heterogeneity can be detected in the ascending albumin boundary after six hours, while after twelve hours definite separation into two components was observed.



6 hr. 12 hr. 22 hr.

ELECTROPHORETIC MIGRATION OF HUMAN SERUM ALBUMINS AT pH 8·0. SERUM DILUTED 1 : 2 WITH BUFFER. PHILPOT-SVENSSON OPTICAL SYSTEM.

We have also observed a small third peak migrating faster than the albumins. This is associated with pigment and lipoids. It is not yet possible to say whether it represents a true protein component.

The two albumin peaks have now been observed in all the five normal sera examined up to the present. The ratio of the mobilities of the two albumins is 1·01, and this value remains constant throughout the experiment.

Previous workers have reported only one albumin boundary at pH 8·0, although Luetscher[1] observed a complex pattern between pH 4 and 6. Moyer and Moyer[2] separated two albumins from horse serum by fractional crystallization and showed that the difference in electrophoretic mobilities was greatest at pH 8·0. The present observations show that human serum also contains at least two albumins, which have not previously been differentiated on account of the small difference in their mobilities.

We suggest that the faster component be termed A_1 and the slower A_2, pending their further characterization, on which we are now engaged.

An Antibiotic Substance in the Chine Water-chestnut, *Eleocharis tuberosa*

IN our search for the presence of antibiotic su stances in the higher plants used in China for fo or for drugs, we have examined the tubers of t waterchestnut, *Eleocharis tuberosa*.

The waterchestnuts, bought in the local mark were washed and crushed in a Carver laborato hydraulic press. In a typical experiment, 1,650 g of waterchestnuts yielded 300 ml. of a milky liqu with a slightly acid reaction (pH 6·3). This w neutralized with a few ml. of $N/10$ sodium hydroxi solution and the antibiotic action of the soluti was tested with the 'ring test' method of Heatle for penicillin. Positive results were obtained wi *Staphylococcus aureus*, *B. coli* and *Aerobacter aer genes*. *Bacillus graveolus* was found to be unaffect under the conditions of our experiments.

The active principle has not yet been extracte and concentration of the liquid extract has thus f been effected by a crude technique[2] because of la of a proper vacuum pump. The active substan is thermolabile, being destroyed when subjected a water-bath temperature of 95° C. for more th 10 minutes. It is not destroyed when kept at pH or pH 8 for at least 30 minutes. In slightly alkalin acid or neutral media, it is not extracted by ethe petroleum ether, chloroform, benzene, carbon sulphide, ethyl acetate, acetone, etc. It is not adsorb by the sample of animal charcoal which we used by kaolin. The activity of the solution appears to destroyed by ethyl alcohol. When the milky soluti is cleared of its protein and other substances with lea acetate, and the latter is removed with hydroge sulphide, the clear neutralized solution gives n activity.

The partially concentrated extract when added t *B. coli* in microrespirometer vessels of the Warbur type inhibited the respiration of the culture mo than 80 per cent after about ten hours.

For convenience, we shall designate the activ antibiotic principle in *Eleocharis tuberosa* as 'puchiin from the Chinese characters for *Eleocharis tuberos*

We are indebted to Dr. G. S. Fan of the Chin Blood Bank for his assistance in carrying out som of the tests on the antibiotic effects of puchiin.

Utilization of Carotene from Oils

VARIATIONS in the growth-response of vitamin A deficient rats to carotene dissolved in different oil has been partly attributed to their linoleic aci content[1]. While trying to discover the causes of th variations, it was felt that it would be of interest t test this hypothesis by equalizing the intake of linolei acid. Rats depleted of vitamin A reserves on a low fat diet similar to that of Sherman[1] were divide into five groups and fed the supplements indicate in the accompanying table by a and b by means o calibrated droppers.

Group	No. of rats used	Supplements	Gain in wt. (gm.)		Pigment excreted (%)		
			5 wks.	7 wks.	Total	Non-carotene	Carotene
I	7	*a* : 3 μgm. β-carotene and 100 mgm. cottonseed oil *b* : 100 mgm. cottonseed oil	25	31	40·5	24·0	16·5
II A	6	*a* : 3 μgm. β-carotene and 100 mgm. arachis oil *b* : 100 mgm. arachis oil	24	32	—	—	—
II B	6	*a* : 3 μgm. β-carotene and 100 mgm. arachis oil *b* : 80 mgm. ethyl linoleate and 20 mgm. arachis oil	24	30	34·2	17·1	17·1
III A	6	*a* : 3 μgm. β-carotene and 100 mgm. coco-nut oil *b* : 100 mgm. coco-nut oil	17	22	26·1	16·2	9·9
III B	7	*a* : 3 μgm. β-carotene and 100 mgm. coco-nut oil *b* : 100 mgm. ethyl linoleate	18	23	23·2	14·6	8·6

The supplements *a* and *b* were fed on alternate days o overcome the antagonism between carotene and noleate[1]. The oils were free from carotene, since ontrol rats receiving 500 mgm. of each in their diet ontinued to decline in weight and died. Since cotton seed oil contains 48 per cent, arachis oil 21 per cent and coco-nut oil 2 per cent approximately of linoleic acid[2], the total linoleic acid intake of rats in groups I, I *B* and III *B* on two consecutive days was almost he same. The ethyl linoleate was kindly prepared by Mr. P. R. Aiyar from sesame oil and had an iodine value 165.

The growth-response in coco-nut oil was much less than in arachis or cottonseed oils. The latter were equally efficient in spite of the wide variation in linoleic acid content. Further, increase in the intake of linoleic acid did not improve the response. It appears that the causes for the variations in response have to be sought elsewhere.

Ramasarma and Hakim[3] reported that rats excreted carotene even when it was administered at the level used in biological assays. Analysis of the fæces of the different groups of rats, collected for a number of days during the experimental period, confirmed their results, and showed that differences in fæcal excretion were too small to explain the variations in growth-response. The non-carotene pigment in the fæces could be separated from the carotene by chromatographic adsorption on a column of Brockman's alumina. The necessary correction was applied by determining the pigment excreted on a carotene-free diet.

The response to carotene has been shown to be improved by vitamin E (tocopherol)[4]. The tocopherol contents of the cottonseed, arachis and coco-nut oils determined by a modification of Moore's[5] procedure were 260, 286 and 0 gm. per gm. respectively. The utilization of carotene, therefore, appears to depend on the tocopherol content. A similar hypothesis has been put forward independently by Guggenheim[6], and experiments are in progress here to test this theory. The higher excretion of carotene with cottonseed and arachis oils may be explained by the antioxidative action of tocopherol in the gastro-intestinal tract. Incidentally, it was confirmed that no loss of tocopherol occurred during the saponification of the oil with alkali in the presence of pyrogallol. The details of these investigations will be published elsewhere.

I am grateful to Prof. V. Subrahmanyan for his interest in the work, and to the Lady Tata Memorial Trust for the award of a scholarship.

Control of Internal Boll Rot of the Cotton Plant, caused by Insect Punctures (*Dysdercus* sp.), through Selection of Resistant Strains

One of the main problems related to cotton production in the irrigated valleys of the northern coastal part of Peru is connected with damage to the crop produced by the cotton stainer (*Dysdercus ruficollis*, L.), which in some years causes a loss of many million soles (1 sol = 1*s*. 1¾*d*. nominal value). The cotton crops of the valleys of Pativilca, Supe, Huarmey, Casma, Santa and Piura-Chira are the most affected annually by the "Arrebiatado" insect.

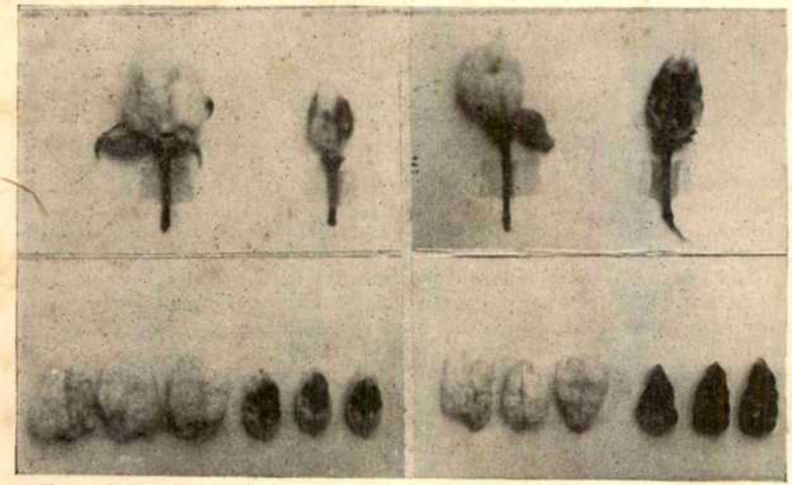
The known methods of control for cotton stainer damage, such as the strict observation of the time of planting and picking, in order to have a period of clean fields during the year, or the destruction of host plants (*Sida panniculata*, *Malachra* sp., and other Malvaceæ), the trapping of insects (a method scarcely used in Peru), or the use of special insecticides like "Babbini", recently developed in this country have had only partial success. Except for the Piura-Chira valleys, where the strict observation of time of planting and picking has led to very encouraging results, there is not known at present a method which will protect cotton plants against that pest.

Following the very interesting results obtained in the Belgian Congo by Dr. R. L. Steyaert[1], we submitted for the approval of the superintendent on February 8, 1945, "A project of phytotechnical investigations concerning the selection of Tangüis cotton strains resistant to the internal boll rot caused by the punctures of the arrebiatado (*Dysdercus ruficollis*, L.) insect". After approval of the project, the investigation started on April 13 in La Molina Agricultural Experiment Station.

The preliminary work dealt with the microorganism found in rotten bolls, naturally infected in the field, through the cotton stainer punctures, and was conducted by the Plant Pathology Service. Isolations from internal diseased bolls and cultures were made from the following micro-organism: *Y*-1 = Bacteria sp.; *Y*-2 = a fungus not yet identified; *Y*-3 = *Alternaria* sp.; *Y*-4 = *Acremonium* sp. Of these, *Y*-3 and *Y*-4 micro-organisms seem to be the most virulent. *Nematospora* sp. have not yet been found.

Then a series of inoculation tests were made on a total of 160 plants, selected from the best strains of the Plant Genetics Department. Four bolls from each plant were artificially infected, each one with a different micro-organism. The work was conducted in the laboratory after taking off the bolls from tagged plants and by submerging the peduncle of the bolls in water to keep them in good condition for an eight-day period. For inoculation, the technique of Dr. Steyaert was followed with minor modifications and proved to be very useful.

Examination of artificially inoculated cotton bolls after eight days showed in a large percentage that their contents were completely rotted. However, a few plants (twelve) from four strains showed 'resistance' to infection, especially the strain No. 16–38 (LM # 7–35 group), as demonstrated by the accompanying photographs.



Upper photographs: COTTON BOLLS ARTIFICIALLY INOCULATED WITH PURE CULTURES OF *Acremonium* SP. (LEFT) AND *Alternaria* (RIGHT). RESISTANT PLANT ON LEFT OF EACH PAIR. *Lower photographs:* LINT FROM BOLLS INOCULATED WITH PURE CULTURES OF *Acremonium* SP. (LEFT) AND *Alternaria* (RIGHT). RESISTANT PLANT ON LEFT OF EACH PAIR.

This investigation was begun on April 13 and continued until the end of the month. It will be continued in the next cotton season, toward the end of the year, with the four strains which were apparently 'resistant' to infection.

Comparing the results obtained by Dr. Steyaert, who worked with American varieties of cotton (*G. hirsutum*, L.) and those obtained by us, working with Peruvian varieties (*G. barbadense*, L., var. *peruvianum*, Cav.), it may be assumed that the latter varieties are genetically more 'resistant' to infection by fungus producing internal rot of the cotton bolls, transmitted by the "arrebiatado" punctures, than the former varieties.

A very interesting field of investigation appears to be opened up by the preliminary results mentioned here for the control by plant selection of cotton stainer damage.

Inheritance and Acquired Characteristic

IN his recent book, "Habit and Heritage" (Kega Paul, 1944), Wood Jones has again directed attentio to the subject of hair-tracts in mammals with speci reference to direction of growth and scratching habi in hairdressing. He points out that in certain marsu ials, the habits of which have been observed an recorded in detail, the characteristic adult deviatio from the primitive cranio-caudal direction of th body pelage are already established in the pouc young. The inference to be drawn from the obviou correlation between direction of growth and scratchin habits of these species, and their predetermine appearance in the pouch-young, is that the modifie direction, originally induced through habit, has be come inherent in the genetic constitution during th course of evolution.

I am indebted to Mr. Albert Hochbaum, direct of the Experimental Duck Station at Delta, Manitob Canada, for directing my atte tion to the following analogou yet essentially different, case i ducks. All adult ducks have wel developed pterylæ (feather-tract and do their preening as system atically as mammals do thei scratching, running their bil along only certain defined lines o the contour plumage in conformit with the distribution of th pterylæ. Preening is, in fact, no a random operation, but deter mined by the extent of the tract and directions of the feathers. At the time of hatching, however, the duckling is clad in down whic exhibits no pterylosis, being evenly distributed over the body as in the supposedly primitive arrangement of adult Ratites and the *Sphenisci*. The contour feathers make their first appearance as sprouts at three weeks and are not fully developed until much later. As early as the age of five *hours* the ducklings (incubator-hatched) may commence to preen. From the start they go through the specific adult motions, although these are quite meaningless during the period of weeks in which the uniformly distributed coat of down is their sole covering. In this case it is not a morphological structure that precedes the appearance of a controlling habit, but a habit that precedes the development of a morphological character, to the topography of which the practice appears to be directly adapted.

Mr. Hochbaum has also pointed out that a young duckling, incubator-hatched and isolated from grown birds, when stretching, does it in the familiar adult fashion as if the primaries were already present; yet it then possesses merely rudiments of wings and no wing-feathers against which to press its outstretched leg. The leg nevertheless goes through the motions appropriate to the adult state.

I should point out that while these facts emanate from Mr. Hochbaum, he is not to be held responsible for the suggested interpretation.

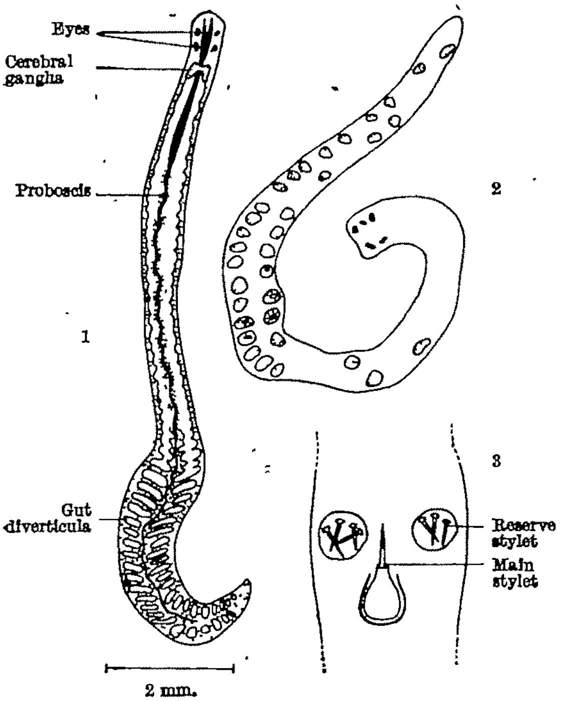
A British Freshwater Nemertine

On July 12, 1944, while collecting planarians in the Cam at Cambridge, we found a small orange-coloured worm in the leaf axils of *Glyceria aquatica* stems. Afterwards many more were found. The general structure, including the proboscis, showed clearly that it was a nemertine. The only freshwater nemertine previously recorded from Great Britain was a single specimen found by Benham[1] in the River Cherwell, of which, however, there is no full description. There is also a single record of a freshwater nemertine from Ireland in Co. Dublin[2]. The present record is therefore of interest.



Prostoma Græcense: 1. Dorsal view. 2. Diagram showing distribution of ova. 3. Main and reserve stylets.

The worms were not uncommon in association with *Glyceria*, it being an easy matter to collect some six specimens in an hour. It was distributed widely in the Cam and its tributaries between Cambridge and Harston, although weirs occur along this stretch of the river. We did not have an opportunity to search beyond these limits, but we were informed that a single specimen had been found in the Great Ouse near Over (September 13, 1944). The worms were still abundant in the Cam throughout the autumn, but had disappeared by November 24, by which time the *Glyceria* with its associated turbellarian fauna was dying down. In July nearly all the individuals contained eggs, though none was found in specimens collected during November. Small isolated specimens have again been found this year, the first on March 21. It is of interest that one of these specimens contained actively moving sperm in the testes.

The worms ranged in size from 5 mm. to 20 mm. in length, and from 0·5 mm. to 1 mm. in width. They were usually orange-red in colour, but yellow and almost colourless individuals were found. In addition the surface was often flecked with brown pigment. The accompanying drawings indicate the general structure of the worms. The mouth and rhynchodæum have a common opening. There are four to eight eyes, the number and degree of development of which is very variable. The few specimens so far sectioned have ten proboscis nerves. There appear to be commonly two stylet sacs, each containing three to five reserve stylets, on either side of the main stylet. The length of the main stylet including the haft is approximately 95 μ.

Allowing for the variability in colour and eye number, the worms agree with the description of *Prostoma* (=Tetrastemma=*Stichostemma*) *græcense* (Bohmig). This species is characterized by the possession of a common opening for the mouth and rhynchodæum (differentiating it from *P. clepsinoides*), and by the possession of ten proboscis nerves (differentiating it from *P. eilhardi*). Bohmig records[3] *P. græcense* from the Botanic Gardens at Graz, and from mud in a stream at Prague. The nemertine recorded by Southern in Ireland was referred by him to the species *P. clepsinoides*. As Hallez points out[4], the two species are closely related. Unfortunately, Benham's single specimen from Oxford was accidentally destroyed before it could be fully identified.

We should be glad to receive any information about the distribution of this freshwater nemertine in other parts of the British Isles.

We wish to thank Dr. C. F. A. Pantin for his interest and help in making these observations.

The Popliteal Facet in Men who Habitually Squat

Some interest has centred around the variations in the lower end of the femur occasioned by the squatting posture[1-4], and the present communication is to record yet another variation in the lower end of femora from Punjabis of lower classes, who adopt the squatting posture not only during work but also during rest. In a series of two hundred femora examined, a curved facet, covered with cartilage, was detected in all of them in the posterior part of the lateral aspect of the lateral condyle. It was well marked in some, less so in others, but was present in all. This facet may be looked upon as an extension of the femoral condylar articular cartilage on the lateral aspect posteriorly, just as the quadriceps facet[1] is an extension of cartilage anteriorly.

The popliteal muscle arising from the anterior end of the popliteal groove on the lateral side of the lateral femoral condyle, and being inserted on the upper end of the posterior surface of the tibia, lies in the popliteal groove during flexion of the knee joint but moves in an arc on the lateral side on the lateral femoral condyle during the movement of extension, until the tendon lies obliquely from before backwards, bevelling the anterior part of its lower border. The friction between the tendon and the side of the condyle is obviated by the synovial membrane acting as a bursa.

As the movements of the knee joint are more frequent in squatting than non-squatting races[1], the popliteal tendon rubs against the lateral condyle much more frequently in the former than in the latter. The popliteal facet seems to owe its existence to this fact.

Effect of High Vitamin A in the Diet of Domestic and Non-Domestic Animals

THE purpose of this study was to learn the specific effect of diets containing medium and large amounts of vitamin A upon the digestive equipment of domestic animals, and of wild animals kept in captivity. Vitamin A has been found to be essential for the development and growth of young animals; quite characteristically it has been found to enhance metabolism and promote assimilation, and thus it is obvious that this very quality results in the promotion of growth and development, for the latter is based upon normal metabolism and the elimination of residual matter in the living body.

The first study was made in connexion with the diet of a thoroughbred German Shepherd bitch which had developed a chronic diarrhœa which had persisted over a long period of time. This dog was fed regularly and was not exposed to infection or to contaminated food. She had no intestinal parasites; her food consisted of the cooked lights (lung), liver and heart from sheep, and the broth therefrom. Evaporated milk diluted with water and dog biscuit were given for the second daily meal. The dog was apparently perfectly well, the coat was heavy and lustrous, her vitality unimpaired. However, the persistent diarrhœa left no doubt that her diet contained something which had the effect of a laxative.

In order to trace the offending factor in the diet, the milk was eliminated first, but put back when found to be inoffensive. The dog biscuit was tested in the same manner, and finally the heart, lung and liver. By the process of elimination it was determined that liver was the substance which was responsible for the diarrhœa. Only two days after elimination of the liver from the diet, the dog had perfectly normal bowel discharges and has remained perfectly well ever since.

Liver is one of the organs of the animal body which stores up vitamins in large amounts. Vitamin A, apparently, contained in the liver, was responsible for the accelerated metabolism resulting, in turn, in diarrhœa in the dog. Other organs, like kidney and spleen, also rich in vitamins, but probably containing less vitamin A, had a similar effect, but not quite so pronounced. The liver, kidney and spleen were more laxative when fed raw than when given cooked, some of the effect of the vitamin being destroyed when exposed to heat.

Later dietary studies were extended to wild rabbits kept in captivity. Many experiments to raise these animals in captivity have failed because of the mistake made of feeding them standard domestic rabbit rations. Wild rabbits, due to their extremely rapid growth during the first few weeks of their life, require unusual amounts of vitamin A. The milk of rabbit does is known to be richer in butter fat (containing vitamin A) than the milk of most other animals. As the rabbits are weaned, they select for their first solid food such weeds which are richest in vitamins A and C, like dandelion and clover, while delicacies such as fresh peas, lettuce and cabbage were steadily rejected by the experimental animals. Another interesting observation was that carrot tops, which were accepted by wild young rabbits when no dandelion was available, resulted, given in large quantities, in diarrhœa and sickness. Carrot tops are known to contain an abundance of vitamin A.

To confirm these findings regarding the laxative properties of vitamin A, concentrates of this vitamin were administered to the dog together with an otherwise normal diet. The effect produced by vitamin A concentrates was the same as that reported for natural foods containing this factor in large quantities. Afterwards, other foods known for their high vitamin A content were tested in relation to their effect upon the digestive tract of animals. Among these foods were: carrots (root), tomatoes, suet, honey and molasses. All these substances confirmed the previous findings that high vitamin A content accelerates metabolism to the point where it causes diarrhœa in cases where large amounts are contained in the food ingested.

Spontaneous Regression of Histologically Malignant Tumours Induced in Rabbits by 9 : 10-Dimethyl-1 : 2-Benzanthracene

BERENBLUM has reported[1] the induction of squamous carcinoma in rabbits with 9 : 10-dimethyl-1 : 2-benzanthracene.

The ears of eleven rabbits were painted with a solution in acetone of 0·3 per cent 9 : 10-dimethyl-1 : 2-benzanthracene (which was kindly supplied by Prof. J. W. Cook), for sixteen weeks, without immediate effect. The strength of the solution was then increased to 2 per cent, after which papillomas in five rabbits appeared within three to six weeks. Clinical evidence of infiltrating growth was noted in three rabbits after further periods of four, seven and sixteen weeks respectively. The tumours measured 1·5–4 cm. in diameter, and extended from their origin on the inner side of the ear to the subcutaneous tissue of the outer side, bulging out the skin. Biopsy of one tumour was done, and reported by Dr. P. R. Peacock as having the appearance of a squamous carcinoma penetrating lacunæ in the cartilage.

Two rabbits were used for therapeutic experiments, but the attempt was abandoned after one injection in one rabbit, and after two injections in the other, because the solution used caused phlebitis. No therapeutic effect was observed within three weeks n the first rabbit, and within four weeks in the second rabbit. After this period, painting was discontinued, and both tumours, as well as the untreated control tumour, regressed completely within five weeks.

The observation suggests that in tumours induced by 9 : 10-dimethyl-1 : 2-benzanthracene in rabbits, as in tar carcinoids, histological malignancy is not necessarily irreversible. These tumours, therefore, may not be classified as truly malignant, in spite of their histological appearances, and are not suited for therapeutic experiments.

Phase Transitions in Condensed Monolayers of Normal Chain Carboxylic Acids

INVESTIGATIONS using a thermostated double-acting recording surface balance of the Wilhelmy-Dervichian type[1,2] reveal an interesting series of phase changes in condensed monolayers of normal chain fatty acids of high molecular weight. As an example, we may take the surface pressure – area curves for *n*-docosanoic (behenic) acid[3] spread on acid (0·01 *N* hydrochloric acid) substrate shown in Fig. 1. At the lowest temperature the solid film gives a smooth pressure – area curve and the area can be reduced down to about 18·6 sq. A. per molecule before a gradual collapse sets in. At this area the chains are evidently vertical and as closely packed as in the normal three-dimensional hydrocarbon crystal, in which the cross-section of the chains[4] is about 18·4 sq. A. This close-packed solid phase may be denoted by *CS*. When the temperature is raised, another phase, L_2, appears[5], the stability range of which increases with temperature. At 8·2° a new phase, which we may call L'_2, appears and is quite marked in the curve for 10° in Fig. 1. At 13·8° the high-pressure phase *S* appears and the curve for 14·8° shows a transition $S \rightleftharpoons CS$ which is rapidly displaced towards higher pressures with raising temperature. Above 18°, *CS* has disappeared and *S* shows a sharp collapse at about 55 dynes pressure. The smallest area at which the phase *S* is stable is about 19·3 sq. A. It seems likely, therefore, that the molecules are vertical and perform strong torsional oscillations[6] or complete rotations, as the area per chain corresponds to that found in hydrocarbon crystals near the melting point[4]. (A few degrees below the melting point some hydrocarbons show a gradual, others an abrupt, change from a state of lower symmetry into one of hexagonal symmetry, in which the vertical chains are rotating about the long axis.)

As the temperature is raised, the transition $L_2 \rightleftharpoons L'_2$ becomes less marked. The transition $L'_2 \rightleftharpoons S$ is of the second order from its first appearance at 13·8°–22°, but over the temperature range 22°–29° the transition from the L'_2 phase is of the first order. Harkins and Copeland[7] have recently studied a similar phenomenon in monolayers of *n*-octadecanol-1. They found a triple point at 7·5° with the appearance of a new phase called *LS*, characterized by a very low viscosity. Over a certain temperature range the transition $L_2 \rightleftharpoons LS$ was of the first order. The existence of an *LS* phase in monolayers of *n*-docosanoic acid is suggested by a decrease in film viscosity (or rigidity; when the chains are very long, both L_2 and L'_2 are solid) at the transition from the L'_2 phase at temperatures above 22°, and by the break in the high-pressure portion of the curves above this temperature (more marked at higher temperatures, see Fig. 1) which is probably due to an $LS \rightleftharpoons S$ transition. It is difficult to determine the order of this transition, owing to instability of the film at the high pressures involved, but it appears to be a second order one. The same also applies to the $S \rightleftharpoons CS$ transition.

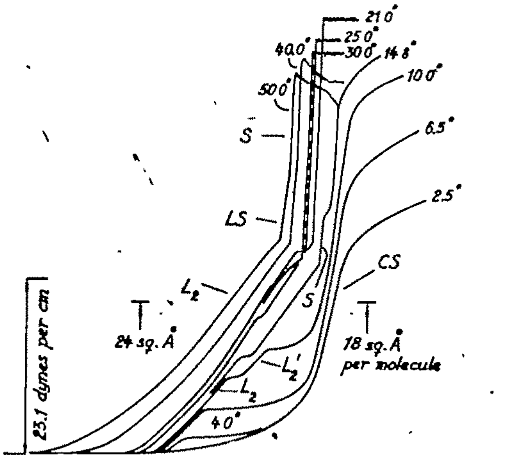

Fig. 1.

Experiments with the Langmuir-Adam balance show that on compression the pressure remains constant over a certain area range during the transitions $L_2 \rightleftharpoons CS$ and $L'_2 \rightleftharpoons CS$, and these are therefore of the first order. There is a certain amount of hysteresis, however, and the curves in Fig. 1, which have been redrawn from automatically recorded curves, are not quite horizontal during the transitions. The transition $L_2 \rightleftharpoons L'_2$ is also of the first order below about 23°, but probably becomes second order above this temperature. The changes in the pressure-area curves are very small, however, and it is difficult to determine the order exactly. Diffuse first-order transitions and

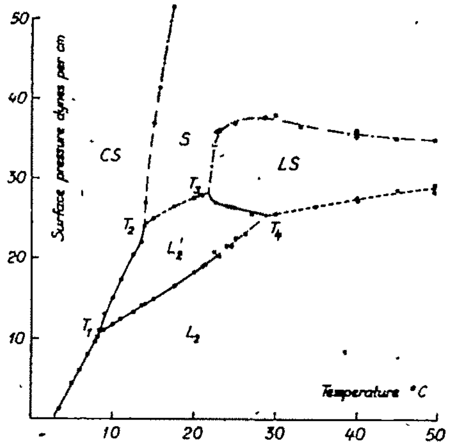

Fig. 2.

third-order transitions in monolayers have been considered by some authors[8], but according to Lifshitz[9] only first- and second-order transitions are thermodynamically possible.

The surface pressure – temperature diagram for *n*-docosanoic acid is shown in Fig. 2. Unbroken heavy lines represent lines of first-order transitions and dotted heavy lines second-order transitions. A dash-dotted thin line indicates that the order of the transition is uncertain. The phases L_1 ('liquid expanded') and G (gaseous) are not included. There are four triple points: $T_1 \sim 8{\cdot}2°$, $T_2 \sim 13{\cdot}8°$, $T_3 \sim 22°$, $T_4 \sim 29°$.

The temperatures at which the various transitions occur are raised by about 5° for each added CH_2 group. If a mixture of acids has the same mean molecular weight as a pure acid, the set of curves given by the mixture will be very closely similar to that given by the pure acid, provided that the chains in the mixture do not differ by more than two carbon atoms in length.

The close-packed *CS* phase has also been found for methyl and ethyl esters of long normal acids and for alcohols and acetates, and will probably be found in other cases, provided that the chains are long enough or the temperature low enough, and the cross-section of the head group is less than that of the chain. *n*-Docosyl acetate shows all the transitions described above for *n*-docosanoic acid. The L'_2 phase has so far been found only for acids and acetates.

A detailed account of the investigation will be published elsewhere.

Infra-Red Spectra of Coals

IN a recent paper on the infra-red absorption spectra of coals[1], we mentioned an unsuccessful attempt to obtain such spectra by examining the infra-red transmission of finely ground coals dispersed in 'Nujol' (liquid paraffin).

A more detailed investigation of the dispersion technique has now given satisfactory spectra. We have found that it is essential to get down to a particle size of the order of 1 μ and to use an effective path-length of at least 50 μ. Although under these conditions the energy transmitted by a 'coal-Nujol' film is so low that large slit widths are necessary to measure the transmission, spectra with quite well defined bands are obtained.

Using this technique, the spectra of a series of coals supplied by the British Coal Utilisation Research Association have been recorded and characteristic differences in the spectra of coals of differing rank and origin have been detected.

A detailed account of this work, which forms part of a programme of fundamental research on the spectra of coals carried out for the British Coa Utilisation Research Association, will be published elsewhere in the near future.

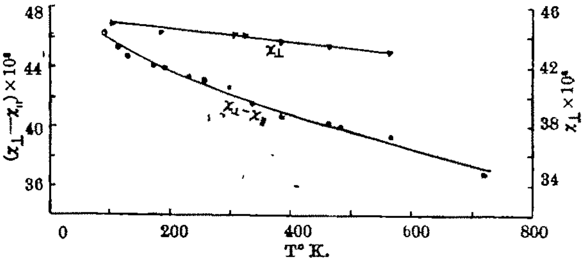
Effect of Temperature on Magnetic Susceptibility of Molybdenite Crystals

THE structure of the molybdenite crystal has been determined by Pauling and Dickinson[1] and Hassel[2]. They found that the molybdenum and sulphur atoms in it are arranged in separate layers perpendicular to the *c*-axis. Each layer of molybdenum atoms has two layers of sulphur atoms on opposite sides of it. The whole structure is then built up by the repetition of composite layers each of which is formed by a molybdenum layer sandwiched between two sulphur layers. The excellent cleavage in a plane parallel to the layers themselves may be regarded as a natural consequence of the large distance between these successive composite layers. In layer structures of this type, it seems that the major portion of the primary valencies is exercised within the layers themselves, and only secondary forces hold the layers together to form the crystal lattice.



In view of the above considerations, magnetic studies on single crystals of molybdenite were undertaken and interesting results[3] have been obtained. The difference between the two principal susceptibilities $\chi_\perp - \chi_\parallel$ has been found to be $42{\cdot}8 \times 10^{-6}$ per gm. mol; and $\chi_\parallel$, the absolute value of the susceptibility along the *c*-axis, being $-87{\cdot}1 \times 10^{-6}$ per gm. mol. Thus the anisotropy is found to have the high value of about 72 per cent. Recently these measurements have been extended to various temperatures both high and low. The results are shown diagrammatically in the accompanying graph. It has been found that there is a large temperature variation of $\chi_\perp - \chi_\parallel$, the difference between the principal susceptibilities. It varies from $46{\cdot}4 \times 10^{-6}$ at about 90° K. to $36{\cdot}8 \times 10^{-6}$ at about 700° K. On the other hand, $\chi_\perp$, the susceptibility at right angles to the symmetry axis, has been found to vary quite slowly with temperature, namely from $-45{\cdot}01 \times 10^{-6}$ at 90° K., to -43×10^{-6} at 566° K. Details of these investigations will shortly be published elsewhere.

Viscosity of Ordinary Liquids at High Rates of Shear

THE viscosity, η, of a fluid can be represented by[1]

$$\eta = \left(\frac{N}{V}\right)^{2/3} \cdot \frac{c.(2.\pi.m.k.T)^{1/2}\, R.T}{E_T} \cdot e^{\frac{E_{\text{visc.}}}{R.T}}, \quad . \quad (1)$$

where N is Avogadro's number ; c is a packing factor ; m is the mass of a molecule ; k is Boltzmann's constant ; $E_{\text{visc.}}$ is the energy of activation of viscous flow ; V is the molecular volume ; E_T is the sum of the potential and the kinetic energy of the molecules. We have found that E_T can be expressed as the sum of the latent heat of vaporization ($\triangle E_{\text{vap.}}$) and a multiple of $R.T$ ($d.R.T$). It has been shown[2] that $E_{\text{visc.}}$ equals the work of cohesion for non-associated liquids, and from this fact it was deduced that $E_{\text{visc.}}$ equals the bond energy between two interacting molecules. Further, it has since been deduced that $\triangle E_{\text{vap.}} = b.E_{\text{visc.}}$, where b is a factor depending on the mean co-ordination. Thus both $\triangle E_{\text{vap.}}$ and $E_{\text{visc.}}$ depend on the number of bonds per mole, formed by the interaction of the molecules.

The number of closed bonds, N', will, apart from the mean co-ordination, be a function of the co-ordination frequency, z, that is, $N' = f(z)$, and to a first approximation $N' \propto 1/z$. In a stationary liquid the molecules are in thermal agitation and z will have a certain value, depending on the temperature. In a liquid under flow, 'agitation of flow' will be superimposed on the thermal agitation. If z_1 is the co-ordination frequency in the stationary liquid and z_2 that frequency in the moving liquid, then f, the ratio of the number of closed bonds in the moving liquid, n, to that in the stationary liquid, N', will be given by

$$f = \frac{n}{N'} = \frac{z_1}{z_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

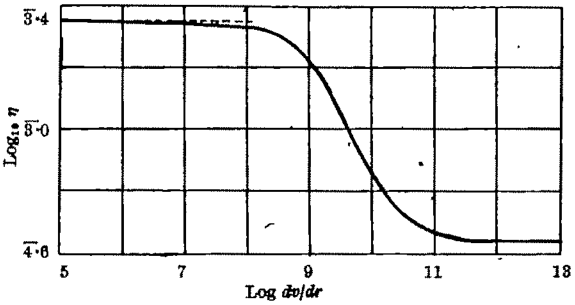
For z_2 one may write $z_1 + z_3$, where z_3 is the increase in co-ordination frequency due to viscous flow. If the molecular layers are moving with relative velocity v_r and the intermolecular distance is λ, then $z_3 = v_r/\lambda$. It is to be noted that z_3 according to this definition is also equal to the rate of shear in the liquid. So long as $z_1 \gg z_3$, the factor f will be practically equal to 1 and $\triangle E_{\text{vap.}}$, $E_{\text{visc.}}$ and η will be independent of the rate of shear. When z_3 approaches values comparable with z_1, f will no longer be unity, and both $\triangle E_{\text{vap.}}$ and $E_{\text{visc.}}$ will be reduced to a fraction f of their value. Then equation (1) becomes

$$\eta = \left(\frac{N}{V}\right)^{2/3} \cdot \frac{c.(2.\pi.m.k.T)^{1/2}\, R.T}{f.E_{\text{vap.}} + d.R.T} \cdot e^{\frac{f\,E_{\text{visc.}}}{R.T}} \quad . \quad (3)$$

To evaluate f: z_3, the rate of shear, is given by the experimental conditions ; z_1 can be obtained approximately from the coefficient of self-diffusion, D ; D will be approximately of the same order of magnitude as the coefficient of diffusion observed in solutions. Using the Stokes-Einstein relation, one obtains

$$z_1 = \left(\frac{N}{V}\right) \frac{k.T}{6.\pi.\eta} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Using equations (3) and (4), the viscosity of n-pentane at 30° C. and at high rates of shear was calculated (see graph). One can see that the viscosity of n-pentane will reveal its dependence on the rate of shear at a value of approximately 5×10^8 sec.$^{-1}$ of the latter.



From equation (4) one can deduce that

$$z_1 \times \eta_0 \times V = \text{constant},$$

at constant temperature and very nearly

$$z_1 \times \eta_0 \times M \sim \text{constant}, \quad . \quad . \quad . \quad (5)$$

where η_0 signifies the 'Newtonian' viscosity and M the molecular weight. The value of z_3 at which the viscosity will become markedly dependent on the rate of shear will be about 10^3 times smaller than z_1. Let $(dv/dr)_{\text{lim.}}$ be the value of the rate of shear at which the effect can be observed, then one may write

$$(dv/dr)_{\text{lim.}}\, x\eta_0 = \frac{\text{constant}}{M} = \text{limiting shear stress.}$$

For n-pentane at 30° C. the limiting shear stress is found to be about 10,000 dynes/cm.^{2}.

From the theoretical considerations brought forward, one may conclude that at high rates of shear the viscosity of 'Newtonian' liquids may be expected to become a function of the rate of shear. The value of the rate of shear at which the effect becomes perceptible depends on the relative magnitude of the thermal agitation of the molecules and the 'agitation of flow'.

Visible Glow Discharge at Very Low Potentials

It is a well-known phenomenon in gas-filled photo-electric cells that, if the cathode is exposed to illumination, a faint glow is visible within the cell at anode potentials well below the striking potential, that is, below the potential at which the self-maintained discharge starts. Owing to the fact that, as a rule, this glow is of low brightness as compared with the light source which is used to cause the photo-electric emission, it is difficult to establish the anode potential at which the glow begins.

This glow can, however, be observed in complete darkness if a photo-cell of the silver–oxygen–cæsium type, which is sensitive to infra-red radiation, is exposed to a light source through an infra-red filter. By experiments with such a photo-cell containing argon, it was found that a glow is visible at anode potentials as low as 18 volts (the current in this case was 1 μamp.), that is, at a potential only slightly above the ionization potential of argon. This means that a glow commences as soon as ionization by collision takes place.

When the anode potential is gradually reduced from higher values to 20 volts the discharge, which at first fills the whole cell, recedes to the immediate neighbourhood of the anode. This effect is to be expected, because at low anode potentials the photo-electrons will not have sufficient energy to cause ionization by collision until they have almost reached the anode.

I am indebted to Dr. G. B. Harrison, of Messrs. Ilford, Ltd., for directing my attention to the fact that in gas-filled photo-cells a glow is visible at low anode potentials if the cells are observed in darkness.

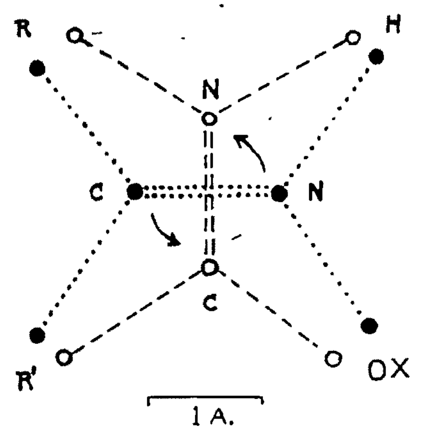
Mechanism of the Beckmann Rearrangement

I have recently received my copy of *Chemical Reviews* for December 1944 and find in it yet one more survey of the Beckmann rearrangement and confession of failure to 'explain the mechanism' in the classical sense.

The diagram shows scale drawings of the oxime before rearrangement (full circles and dotted lines) and the *RN* : *CR*'OX resulting from the change (open circles and dashed lines) superimposed so as to have the same centre of gravity, and minimum rotational movement of the heaviest parts. Both compounds are represented with a proton attached to the nitrogen atom: this is probably the case under most reaction conditions, but is not a necessary feature of the views advanced here. It will be seen that it is only the carbon and nitrogen atoms which move an appreciable distance. The only other movements required are of the atoms directly attached to these, and these movements can all be taken up in the first instance by a 10° bending of the links. The contribution of this to the activation energy can be estimated from the spectroscopic data on bending frequencies —which are mostly of the order of 600 cm.$^{-1}$—and amounts to between 20 and 50 kcal./mole depending on the masses of the attached atoms.

The 'mechanism' of a reaction in the classical sense means the order in which valency bonds are broken and made. We are familiar with a partial abandonment of this in the recognition that in a reaction such as halogen exchange between halide ions and alkyl halides there is a simultaneous 'make' of one link and 'break' of another, and it is further recognized that whenever the activation energy of a reaction is less than the dissociation energy of the bonds which are broken, some such simultaneous make-and-break occurs. In more detail, as the nuclear configuration passes from that of the reactants to that of the products, it passes through an intermediate or transition form which may be regarded as a distortion of either. Therefore distorted forms of the initial and final bond systems are both possible approximately canonical forms for the electronic configuration in the transition state, and the actual configuration will be a resonance hybrid of these. This results in a diminished restoring force or 'weakness' towards any thermal vibration which tends to carry the reactant over into the product.



● ......, atoms and bonds before reaction.
○ - - - -, „ „ „ after „

The description of the previous paragraph applies word for word to the Beckmann change. However, (1) it is probably necessary for the slow thermal movements of the attached groups to be in a favourable phase for reaction to occur (otherwise larger bending of the links is involved) and (2) when reaction does occur the number of bonds made and broken is relatively large, so that the reaction appears complicated. But it is essentially a one-stage mechanism defying further analysis, and, moreover, the word 'migration' is an extremely misleading term. The mechanism as outlined explains all the qualitative features of the Beckmann and allied reactions—the intramolecularity, the *trans* migration, and so on, and also semi-quantitatively the effects of substituents in the groups. It may be added that a similar explanation can be drawn up for the pinnacol-pinacoline group of rearrangements, including as a natural consequence the Walden inversion which occurs on the carbon atom which remains capable of optical activity.

SOME FRENCH AND GERMAN GEOGRAPHICAL AND GEOLOGICAL INSTITUTIONS

By Dr. JOHN W. WELLS
(The Ohio State University)

THE following notes, which may be useful to geologists and biologists, were compiled during a series of visits in the past few months to several museums and universities in Europe, while I was attached to the U.S. Army. I have been to all of those mentioned below, with the exceptions of Monaco and Berlin. All German universities seen were operating at about half pre-war enrolment during the winter semester 1944–45.

France

Monaco. The director of the Oceanographic Museum, Dr. Richard, died in February. His successor is Commandant Rouch. The Museum is said to have been slightly damaged by the explosion of a 'porpoising' torpedo last summer.

Paris. Prof. E. de Margerie, now in his early eighties, is well, and is actively engaged in the publication of his memoirs ("Critique et Géologie"), a four-volume quarto historical survey of the development of some aspects of geological and geographical science since 1884. The first volume has appeared recently (Armand Colin, 500 fr.). The others are in advanced stages of preparation and publication.

No important changes have occurred at the Sorbonne or the École des Mines. At the Jardin des Plantes the director of the Laboratoire de Paléontologie is now Dr. Arambourg.

Strasbourg. Most of the University staff, including the Service Géologique d'Alsace, headed by Dr. G. Dubois, were evacuated to Clermont-Ferrand during 1939–40. Geological and geographical books, maps and specimens left in Strasbourg were used by the Germans, and the choice things taken into Germany proper. Prof. O. Haas, whose personal library and collections from central Africa are intact, alone remained behind throughout the occupation. The geological building is undamaged by bombing.

Germany

Berlin. At the Bavarian Geological Survey, I met two geologists, one Dutch, the other German, who had been in Berlin as late as February 1945. They stated that: the Preussische Geologische Landesanstalt and the Museum für Naturkunde are quite destroyed; the library and archives of the former were safely evacuated, but only a few types were saved from the Museum; the splendid skeleton of *Brachiosaurus* is lost; at that time both Prof. O. H. Schindewolf and Prof. H. Stille were well and active. This information seems authentic.

Bonn. The Geographisches Institut is a total loss, but its contents had been mostly evacuated across the Rhine. The Geologisch-Paläontologisches Institut is damaged somewhat by blast, but all important collections, such as that of Goldfuss, were safely evacuated. Prof. H. Cloos is still director.

Cologne. The Geographisches Institut is badly damaged, and the contents were not evacuated.

Darmstadt. The Geologisches Institut and Hessische Geologische Landesanstalt were totally wrecked.

Erlangen. Undamaged. Nothing evacuated from the Geologisches Institut. Most of the staff, with the exception of Prof. L. Krumbeck and another, in the German army.

Frankfurt A/M. The Geologisches Institut of the Goethe University is wholly demolished, and the Senckenberg Museum is reduced almost to a hollow shell. The material was mostly evacuated, and, in the case of the Senckenberg, all research collections and stocks of publications and library are safe. Dr. R. Richter, the director, was in Bucharest when that city capitulated, and is now interned by the Russians. Two years ago he published an extensive paper on the rules of zoological nomenclature and nomenclatural problems, "Einführung in die Zoologische Nomenklatur durch Erlauterung der Internationalen Regeln", *Senckenberg. Naturf. Gesellsch.*, 1943 [a copy is now in the British Museum (Natural History) Zool. Dept. Library]. The acting director is Dr. H. T. Reuling. The only actual losses at the Senckenberg Museum, besides the building, were a number of large plaster casts (including the large one of *Diplodocus carnegiei*) and a large ornithological collection. The Senckenberg authorities have carefully saved their publications ordinarily destined for the countries of the Allied Nations, and are hoping to be able to distribute them.

Heidelberg. Undamaged, but most of the collections of the Geologisch-Palaontologisches Institut were evacuated, including large quantities of material from the Mauer deposits. For the last few years there have been three regular staff members, of whom only one, Dr. Florian Heller, was there at the time of my visits. Prof. J. Wilser is head; additional teaching aid was given by Dr. Salomon and Dr. E. Jaworski.

Innsbruck. The University is undamaged. The Geographisches Institut, headed by Prof. H. Kinzl, is in working condition, although most of the non-current library was evacuated. The collections and library were largely evacuated from the Geologisch-Palaontologisches Institut in the Alte Universitat, and are now being moved in again. The Mineralogisches und Petrographisches Institut, still presided over by Prof. B. Sander, is carrying on.

Jena. The Mineralogische Anstalt is totally demolished and apparently was not wholly evacuated before the main bombing three weeks before the fall of the city. The Geographische Anstalt, mostly evacuated, was somewhat damaged by blast. The building temporarily houses the Geologisches Institut of the University of Breslau. No information about staff.

Munich. The main University building is very badly damaged. The Geographisches Institut is relatively undamaged, but rooms have been taken over by the Universitäts-Kanzlei. The Technische Hochschule is not badly damaged; Dr. Wilhelm Credner has been very active during the War, like most German geographers.

The Bayerische Akademie building is a total wreck, and of the vast geological, palæontological and mineralogical collections, only about 250 cases, a very small part, were saved. All the fossil vertebrate collections were destroyed, as well as the Zittel Collection. The building of the Geographische Gesellschaft was wholly destroyed and the entire library lost.

Würzburg. The Geographisches Institut is completely demolished, but most of the equipment had apparently been moved to the country. The Mineralogisch-Geologisches Institut was slightly damaged by blast, nothing evacuated; and, being one of the few habitable buildings in the city, is now used for billeting. No staff members seen.

USES AND LIMITATIONS OF PENICILLIN

RECENTLY brief summaries were given in this journal of some of the work which has been done on the absorption, excretion and local application of penicillin (*Nature*, **155**, 341, March 17, 1945) and on its remarkably successful use for the treatment of syphilis and other spirochætal infections and also of gonorrhœa (*Nature*, **155**, 459, April 14, 1945). Since those articles were written, many reports on its use have appeared, and some of them are summarized below.

Much recent work has been concerned with the limitations of penicillin. Apart from the failure of penicillin to act upon the organisms which cause tuberculosis, cholera, plague, malaria, smallpox and other serious diseases of man and animals, one of its limitations is the inadequacy of the supply of it and the difficulties of the large-scale manufacture of it. There are, however, many indications in the medical and scientific Press that enough penicillin will, before long, be available for dealing with all the illnesses which can be successfully treated with it. The *Lancet* (408, March 31, 1945) notes that the largest plant in the world for the production of penicillin is now being erected at Speke, near Liverpool, but the Ministry of Health does not expect that penicillin will be available just yet through ordinary commercial channels. E. W. Flosdorf (*Brit. Med. J.*, 216, Feb. 17, 1945) gives a technical account of the process of drying penicillin by sublimation as used in the United States and Canada; he discusses, with references to the literature, the problems encountered, and compares them with those presented by the drying of blood plasma. H. Welch *et al.* (*J. Inf. Dis.*, **76**, 55; 1945) have studied the relative toxicity of seven different salts of penicillin and have placed them in the following order of increasing toxicity: sodium, lithium, ammonium, strontium, calcium, magnesium, potassium. All seven salts were equally effective in the treatment of pneumococcal infections of mice.

One limitation of penicillin is its instability (see *Brit. Med. J.*, 272, Feb. 24, 1945), especially when it is made up in the form of pastilles, creams and ointments. It seems likely (see below) that this difficulty may soon be overcome. Of some importance also is the report by S. T. Cowan (*Lancet*, 178, Feb. 10, 1945) that some kinds of rubber inactivate a considerable portion of the penicillin exposed to them and that there is ample time, during the intramuscular administration of penicillin through some kinds of rubber tubing, for the destruction of 25–50 per cent of the penicillin. Cowan describes a simple method of testing the action of rubber tubing on penicillin. Possibly this difficulty will be overcome by the use of tubing made of plastic materials which is now becoming available for surgical work.

Another limitation of penicillin, less easy to overcome and requiring the use of relatively large quantities of the drug, is the fact that, although it rapidly enters the blood and quickly establishes an antibacterial concentration there, it is very rapidly excreted, so that it must be administered continuously (see *Nature*, **155**, 341, March 17, 1945). For this reason it has been found that the best method of giving penicillin is to inject it into the muscles, either by continuous drip or at intervals of three hours or so. This method necessarily gives the subject much pain and discomfort, and disturbs the rest necessary for recovery. Further, penicillin given systemically in this way may fail to reach organisms walled off by inflammatory reactions or lying in the recesses of septic wounds and in bony tissues. Efforts have therefore been made to devise better methods of getting penicillin into that close contact with infecting organisms which it requires for its action. Such methods would at the same time avoid the use of the large quantities of the drug required by systemic administration.

One method of avoiding the pain and disturbance of parenteral administration which has had some success is giving by the mouth. The difficulty here is that penicillin is destroyed by the acid of the gastric juice and by enzymes of the bacteria commonly present in the lower bowel (*Lancet*, 214, Feb. 17, 1945). C. H. Rammelkampf and C. S. Keefer (*J. Clin. Invest.*, **22**, 425; 1945) showed that penicillin *in vitro* is not destroyed by saliva, bile, succus entericus or pepsin, and that, if it is given by duodenal tube, more of it enters the blood than if it is given by the mouth. A. H. Free *et al.* (*Science*, **100**, 431; 1944) showed that, if large doses (100,000 units) are given by the mouth to normal people, 8–33 per cent of the penicillin can be recovered from the urine; but if an alkali (sodium bicarbonate) is given with the penicillin, the amount of penicillin recovered from the urine is reduced, not increased. Penicillin is, however, inactivated more quickly by alkali than by acid. C. J. H. Little and G. Lumb (*Lancet*, 203, Feb. 17, 1945) mixed penicillin with raw egg, milk, plasma and other substances in an endeavour to overcome the effects of the *p*H of the alimentary canal upon it and reported that, if volunteers were given a dose of alkali (sodium bicarbonate or magnesium trisilicate) followed by a quarter of a pint of milk, and ten minutes later penicillin dissolved in saline and mixed with raw egg, a satisfactory antibacterial concentration is obtained in the blood. Their treatment of cases of tonsillitis by this method appeared to be satisfactory and they are trying it with cases of pneumonia, gonorrhœa and surgical sepsis. The same result was obtained with patients suffering from both achlorhydria and hyperchlorhydria. N. G. Heatley (*Lancet*, 590, May 12, 1945) repeated the methods of Little and Lumb and found that his results agreed in general with those of Rammelkampf and Keefer, but he could not confirm the levels of blood concentration and urinary excretion obtained by Little and Lumb. He suggests that the differences may be due to the methods of assay used. He did find, however, that the administration of penicillin in raw egg after bicarbonate and milk produced considerably higher levels of blood concentration and urinary excretion than administration of it in water; he suggests that this method may be effective for the treatment of gonorrhœa, although a dose at least three times as great as that now given by injection for this disease may be necessary. Gyorgy *et al.* (*J. Amer. Med. Assoc.*, **127**, 639; 1945) obtained cures of gonorrhœa by giving doses of 15–20,000 units of penicillin every three hours for two or three days with sodium citrate. J. C. Krautz, jun., *et al.* (*Science*, **101**, 618; 1945) find that aluminium aminoacetate is suitable for the oral administration of penicillin.

It does not follow, as the *Lancet* (597, May 12, 1945) points out, that results obtained with gonorrhœa will apply to other diseases, because gonorrhœa responds more consistently and rapidly to peniillin than any other infection. However, R. L. J. ibby *et al.* (*Science*, **101**, 178; 1945) obtained n inhibitory level of penicillin in the blood for ix hours by giving penicillin in cotton-seed oil by he mouth. W. MacDermott *et al.* (*Science*, **101**, 228; 945), on the other hand, had no success with the ethod of Romansky and Rittman (see *Nature*, **155**, 41, March 17, 1945) of giving penicillin by the outh in peanut oil and beeswax in order to prolong ts action in the body.

Other methods of administration which seek to liminate the pain and disturbance of parenteral dministration of penicillin, and also to put the enicillin into closer contact with the organisms conerned, develop the principle of its local application. he necessity for the close contact of penicillin with he organisms concerned, which arises perhaps from ts apparent mode of action, has been often demontrated by the failures of penicillin given parenterally o affect organisms walled off in abscesses or proected by other tissue reactions, by dead tissue and y their position in the recesses of bone. R. Mowlem *Brit. Med. J.*, 517, April 15, 1945) discusses the use f penicillin in infections of the mandible, concluding hat it is not likely to control infections there when equestra and unfavourable surgical conditions are resent. It is no substitute for surgery, as contriutors to the penicillin issue of the *British Journal of urgery* (see *Nature*, **154**, 677, Nov. 25, 1944) have lso pointed out.

Very recently Lady Florey and N. G. Heatley *Lancet*, 748, June 16, 1945) reported an important levelopment of the local application of penicillin. They set out to discover whether penicillin injected nto abscess cavities (in which, as several other workers have also shown, it may rapidly produce a terile pus and promote healing) would not only act ocally but also would be absorbed into the blood and would establish an antibacterial concentration there. They injected it into the pleural cavity of most of their patients, but they injected it also into the kneejoint and intrathecal space of others, as well as into abscess cavities. They found that penicillin injected at the rate of 120,000 units in 24 hours into the pleural cavity, after aspirating off the pleural effusion there, produces an antibacterial concentration in the blood which lasts for 24 hours or more; injection of 120,000 units into two intact but infected knee-joints also produced an antibacterial concentration in the blood for at least 13 hours in one patient and for 24 hours in the other. The dose for children up to eight years is calculated on the basis of 1,000 units per lb. of body weight per 24 hours. An antibacterial concentration in the blood was also obtained by the injection of penicillin into an abscess cavity in a case of streptococcal septicæmia with multiple foci of osteomyelitis. Penicillin given every three hours through a tube leading into the abscess cavity kept up an inhibitory level in the blood and cured the patient. Later an abscess of the breast was successfully treated by local instillation of penicillin. The publication by these authors of their successful clinical trials of this method of combining the local action of penicillin with its "protracted systemic effect due to the slow absorption" from abscesses and serous cavities will be awaited with great interest. These authors also injected penicillin into the intrathecal space and again obtained an inhibitory level in the blood. After injection of 120,000 units into two adults and its equivalent into one infant, this level lasted for fifteen hours. The authors do not, however, recommend this intrathecal route until purer forms of penicillin are available and until we know more about the effects of penicillin on brain tissue.

Dorothy Russell and Diana Beck (*Lancet*, 497, April 21, 1945), as a result of their work on the local action of penicillin and sulphamezathine on the brain of rabbits and of a mixture of these two drugs, do not recommend the use of penicillin alone for local application to the brain, although sulphamezathine alone, is very bland in its effects and is in this respect comparable to sulphanilamide and sulphapyridine. The *Lancet* (439, April 7, 1945) states that J. V. Cooke and D. Goldring (*J. Amer. Med. Assoc.*, **127**, 80; 1945) have found that after repeated intramuscular injections of penicillin into children with chronic nephritis, penicillin was found not only in the blood but also in the ascitic fluid and in the fluid of the subcutaneous œdema, although the concentration of it in the cerebrospinal fluid was much lower than that in the blood, and intrathecal injections of penicillin did not increase its level in the cerebrospinal fluid.

Work of this kind has an obvious bearing on the treatment of various forms of meningitis with penicillin. Its use for this purpose has already been noted in *Nature* (**155**, 341, March 17, 1945). The treatment of meningitis with penicillin and sulphonamides was discussed at a meeting of the Royal Society of Medicine (see the *Brit. Med. J.*, 378, March 17, 1945) and some of the difficulties encountered are there noted. Sir Alexander Fleming (*Lancet*, 434, Oct. 9, 1943) successfully treated streptococcal meningitis by intrathecal injection of penicillin by the lumbar route. C. H. Rammelkampf and C. S. Keefer (*Amer. J. Med. Sci.*, **205**, 343; 1943) found that after the injection of 10,000 Florey units penicillin was detected in the cerebrospinal fluid for 31–35 hours, and that it was more rapidly absorbed into the cerebrospinal fluid in subjects with meningitis and was detectable there for twenty-hour hours after the injection. The meningitis subjects showed no untoward effects after intrathecal injection, but normal subjects suffered from headache, vomiting and increased intrathecal pressure. C. Pilcher (*Ann. Surg.*, **119**, 509; 1944) found that intrathecal injection of penicillin causes transitory but not serious meningeal irritation, and is most effective for treatment of staphylococcal and meningococcal meningitis when it is given intrathecally; but that sulphathiazole applied locally to the brain may cause convulsions. D. Genge (*Brit. Med. J.*, 369, March 17, 1945) has reported on the treatment by the intrathecal route of two cases of pneumococcal meningitis.

In an Annotation, the *Lancet* (696, June 2, 1945) notes that R. L. Nelson and L. Duncan (*Bull. Johns Hopkins Hosp.*, **75**, 327; 1944) treated syphilitic meningitis by intramuscular injection of 600,000–4,000,000 units of penicillin with excellent results. They preferred intramuscular injection to the intrathecal route. Very recently, P. Forgacs and R. I. Hutchinson (*Lancet*, 786, June 23, 1945) recorded the cure of one case of meningitis due to *Hæmophilus influenzæ* of the smooth type (Pittman type *b*) by giving a combination of intramuscular penicillin and sulphadiazine. The rough type of *H. influenzæ* is not penicillin-sensitive. A. J. Waking and M. H. D. Smith (*J. Amer. Med. Assoc.*, **126**, 418; 1944) consider that penicillin and sulphonamide given together act better on pneumococcal meningitis than either alone.

Reports of allergic reactions to penicillin are not numerous. W. Mitchie and H. W. C. Bailey (*Brit. Med. J.*, 554, April 21, 1945) point out that they are much less numerous than allergic reactions to the sulphonamides. These authors record one case of sensitivity which was confirmed by application of penicillin to the undamaged skin of the arms, with the production five hours later of a kind of weeping eczema similar to that which had appeared on the wounded leg of this subject after treatment of the wound with penicillin dressings.

For the treatment of septic burns penicillin cream is regarded by the Medical Research Council's Burns Unit working at Glasgow (Med. Res. Council Special Report Series, No. 249. "Studies of Burns and Scalds." H.M. Stationery Office, 1944. 4*s*. net) as being the most certain method of eliminating hæmolytic streptococci and staphylococci. Propamidine creams were also very good but were not so effective as the penicillin creams, of which the formulæ are given. After application of a cream containing about 120 units of either sodium or calcium penicillin per gram of cream, hæmolytic streptococci disappeared from 41 out of 54 burns and did not reappear. One advantage of penicillin creams as compared with sulphonamide creams is that the serious risk of absorption of too large a dose of sulphonamide from the raw burned area is eliminated. Penicillin creams may, however, become infected by airborne organisms, such as *Pseudomonas pyocyanea*, which produces a penicillinase which decomposes penicillin. Prof. H. Berry (*Lancet*, 410, March 31, 1945) suggests that this difficulty may be overcome by the addition of 2 per cent of phenoxetol to the cream. Phenoxetol (see *Nature*, **154**, 631, Nov. 18, 1944) attacks especially some of the Gram-negative and penicillinase-producing organisms which are not affected by penicillin, so that such a cream would not only help to preserve the potency of the penicillin cream but would also enhance its value by attacking organisms in it not sensitive to penicillin.

The administration of penicillin by inhalation of it in the form of an aerosol is described by N. Mutch and R. C. Rewell (*Lancet*, 650, May 26; 1945) and by F. A. Knott and W. H. Clark (*Lancet*, 468, April 14, 1945); R. B. Coles, A. N. Barker and E. A. Robertson (*Lancet*, 720, June 9, 1945) describe their use of penagar, which is 0·5 per cent watery agar containing the required dose of penicillin. It is not sticky, it retains its potency for a month in a refrigerator and can be put up in sterile bottles and collapsible tubes. Penicillin readily diffuses through the agar. The authors quote work which indicates that penicillin given in oils, creams and ointments is released too slowly and its diffusion is not good.

The use of penicillin for gas gangrene has been already noted (*Nature*, **155**, 341, March 17, 1945; and **154**, 677, Nov. 25, 1944). G. H. Fisher, M. E. Florey *et al.* (*Lancet*, 395, March 31, 1945) discuss in an important paper its use against clostridial infections. They argue that penicillin should be given for the prevention of gas gangrene rather than for its treatment when it is established, and record evidence which indicates that an inadequate prophylactic dose of penicillin may cause a serious clinical picture very different from that of gas gangrene or anaerobic cellulitis. After a short interrupted course of penicillin, a profound and protracted toxæmia may result and the diagnosis of gas gangrene may be missed; so that the patient fails to get either gas gangrene antitoxin or further doses of penicillin. The local application of penicillin provided protection unt surgical treatment was possible. C. Grimshaw an L. Stent (*Lancet*, 434, April 17, 1945) report on th successful treatment with penicillin of one case post-operative cutaneous gangrene.

The use of penicillin for the purpose of obtainin bacteria-free cultures of protozoa has been know since 1944. A. H. Mahmoud (*Ann. Trop. Med. Hyg* **38**, 219; 1944) successfully used penicillin t eliminate bacteria from cultures of *Trichomona fœtus* of cattle. Penicillin added to Kerr's mediu for the cultivation of this protozoan to give a fin dilution of 30 units per c.c. eliminated streptococ and staphylococci, but did not remove *Prote pseudovulgaris*. *Tr. fœtus* grew in the absence bacteria, and cultures of it were maintained. Pen cillin has also been used by S. Adler and R. J. V Pulvertaft (*Ann. Trop. Med. and Hyg.*, **38**, 188; 1944 to obtain bacteria-free cultures of *Trichomona vaginalis* of man. Sterile cultures of *Trichomona hominis* can be obtained by the method of S. Adle (*Trans. Roy. Soc. Trop. Med. and Hyg.*, **35**, 219 1942), by which this organism is first grown on medi containing prontosil rubrum and then injected wit prontosil into the peritoneum of mice; whereupo the mice get rid of the remaining bacteria and th Trichomonas can then be grown on sterile media But the method is not applicable to *Trichomona vaginalis*, because this species does not survive in th mice for longer than twenty-four hours. The use o penicillin removes this difficulty and makes bacteria free cultures possible.

G. LAPAGE.

PLANT STUDIES IN SYRIA

IN the scientific world, Syria is gaining prominenc chiefly with several important botanical studie made by the botanists of the Hebrew University a Jerusalem, where a representative Syrian collectio has been compiled in the Herbarium, and by severa expeditions of naturalists in the British Army who have collected specimens of fauna and flora for the British Museum under an Army organization known as the Middle East Biological Scheme. There are four great deserts in the Middle or Near East—Sinai, Negeb (Palestine), Judea and the adjacent Ghor (the 'Avrah), southern Iráq and the Syrian desert (which includes part of Transjordania)—available for investigation.

In the course of recent floristic studies in Syria and Palestine, several stations of an interesting tree, *Pistacia atlantica*, Desf., previously unknown in Asia, have been discovered (Zohary, *Palestine J. Bot.*, Rehovat Series, **3**; May 1940). This is one of the most important North African trees. Thousands of the trees were found by Prof. Zohary covering mountain-sides in northern Syria, and desert specimens were well developed. The tree was formerly more abundant, and is limited to more or less mild Irano-Turanian conditions, at altitudes from −30 m. to +1,400 m. Its discovery in a steppe region not suitable for irrigation culture of other plants has given rise to economic interest.

Prof. Zohary has also identified the "Ghada" tree of travel literature from the north Arabian and south Syrian deserts as *Haloxylon persicum* Bge. (*Palestine J. Bot.*, Jerusalem Series, **1**; 1940). This tree, which is of economic value for fuel, is of considerable phytogeographical interest, for its discovery in these deserts suggests affinities of these deserts with those of Central Asia. It is the only tree dominant for housands of square miles which does not normally receive more than 25 mm. of rainfall annually and s entirely destitute of aboreal plant communities away from wadis, except for *Haloxylonetum persici*; he discovery of this tree also suggests possibilities of economic development of the sterile deserts for fuel, charcoal, food for desert livestock and checking and movements.

Considerable knowledge of the flora of the Syrian desert in general is being accumulated in the Department of Botany of the Hebrew University, where a mass of new material awaits publication and adds onsiderably to the information in Dinsmore's 1932 edition of Post's classic "Flora of Syria, Palestine and Sinai", which the American University of Beirut published. Prof. Zohary has carried on the field tudies of the late Prof. Eig and notable publications have been his "Geobotanical Analysis of the Syrian Desert" (*Palestine J. Bot.*, Jerusalem Series, **2**; 1940) and "To the Knowledge of the Flora of the Syrian Desert" (**1**; 1939) which covers the flora of the central part of the desert, with a rainfall of 95–210 mm. annually, and where 175 species were collected, 75 per cent of which were annuals, sometimes exclusively predominating over immense stretches. Some three hundred new species have been added o the flora of Iraq, of which about two hundred are new to science. The Syrian desert flora has been divided into three territories: Mediterranean, Irano-Turanian (the most important) and Saharo-Sindian with 520, 588 and 239 species respectively; also there are 24 Sudano-Deccanian species, 10 Euro-Sibero-Boreoamerican, and 659 species belonging to two or more groups. Prof. Zohary's paper was the first to treat the vegetative character of the country.

MASS MOVEMENT OF THE WATER SHREW, *NEOMYS FODIENS*

IN the *Journal of the Society for Preservation of the Fauna of the Empire* of June 1945 is a remarkable account by Lady Seton (a keen field naturalist and wife of that well-known observer the late Sir Malcolm Seton) of a movement of the water shrew, *Neomys fodiens*. In it she tells how she saw large numbers of this little mammal swimming up a small stream in Upper Teesdale in what appeared to be a mass migration. Migration is so exceptional among land mammals, if not marine ones (unlike birds in which it is so usual we may say it is the rule rather than the exception), that any instance is of outstanding interest.

Such mammalian migration as occurs is of two types: seasonal on the lines of bird migration, the North American caribou being the classic example, and occasional as in the case of the lemming, *Lemmus lemmus*, with its periodic emigrations from the high fields to the low country. These are seemingly initiated by pressure of numbers and scarcity of food, and the travellers appear to be driven by an urge to go downhill. I have watched the little animals scuttling along, each taking its own course and acting independently of fellow lemmings. I have never seen them moving in droves.

The especially interesting part of Lady Seton's account of the shrews she watched is the mass of animals. This is the more noteworthy for the fact that though *Neomys fodiens* is widely distributed throughout the mainland of Britain, it is usually only met with in sparse numbers. The only reference to water shrews in any number I can find is in Barrett-Hamilton's "History of British Mammals", wherein he refers to them living in family parties, and adds, "Probably, also, the breeding season brings these shrews together in companies, which would account for the party of nine or ten encountered by the late Canon H. B. Tristram on May 6, as well as for a concourse of twenty or thirty observed in Yorkshire by Mr. W. B. Arundel on the 10th of the same month". But these are not described as being on the move. Migration does not appear to have been noted by previous observers in this or allied species. Thirdly, Lady Seton's water shrews were swimming upstream and therefore uphill, though why and where to we have no clue.

FRANCES PITT.

SERUM PROTEINS IN THE ULTRACENTRIFUGE

THE monograph on the proteins of blood serum by Kai O. Pedersen*, from Prof. Svedberg's laboratory at Uppsala, brings home forcibly the present complexity of the subject. Although any one of the usual methods of analysis gives apparently clear-cut fractions, each fraction when analysed by some other method usually turns out to be a mixture. The obvious remedy, to fractionate by each method in turn, is impracticable because some of the analytical methods are difficult to use in a preparative way. After a heroic attempt to achieve a complete separation, chiefly by means of ammonium sulphate with ultracentrifugal analysis, Dr. Pedersen had to confess defeat.

But a wealth of new knowledge has been gained, such as Dr. Pedersen's discovery of the new low-molecular globulin 'fetuin', which was described in *Nature* of November 4, 1944. This is present in fœtal serum of ruminants to the almost complete exclusion of the ordinary globulins and antibodies, which only appear after the animal has received colostrum. The same is true to a less marked extent in rodents and man. The discovery of fetuin is due to the ultracentrifuge, because in salting-out and in electrophoresis it behaves like ordinary α-globulin. A fœtal hæmoglobin has been known for some time; but a fœtal serum globulin was unsuspected.

Dr. Pedersen's study of the 'X-protein' is also illuminating. It has long been known that in undiluted serum some of the globulin sediments at the slow rate characteristic of albumin. This is surprising because a complex of the two proteins would normally sediment more rapidly than either component. Dr. Pedersen's explanation is that there is indeed a complex, but that it contains lipide, which decreases its density and therefore its sedimentation rate. The density is so low in human serum that with added salt the complex sediments upwards and can be isolated. This 'density-effect' cannot be observed in other sera, and similar interactions between apparently lipide-free proteins remain unexplained, so that the story still seems incomplete. 'X-protein' seems to be of physiological importance for lipide transport.

FORTHCOMING EVENTS

Tuesday, August 28

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Conversation and the Exhibition of Specimens.

Friday, August 31—Sunday, September 2

SCIENTIFIC FILM ASSOCIATION (at the Technical College, Huddersfield)—Conference on "The Film in Science".

Friday, August 31

At 6 p.m.—Civic Reception by His Worship the Mayor of Huddersfield; at 7 p.m.—Dorothy Grayson: "The Science Film in Education".

Saturday, September 1

At 9.45 a.m.—Mr. W. F. Andrews: "The Film in Industry", 1: "Scientific Film Needs in Technical Training"; Mr. H. Richmond "The Film in Industry", 2: "Film Strip in Technical Training": at 2 p.m.—Mr. Derek Stewart: "The Film as an Instrument of Scientific Research"; at 7.30 p.m.—Mr. Frank Goodliffe: "Film Production".

Sunday, September 2

At 10.30 a.m.—"The Film in Medicine" (Film Show and Discussion); at 2.15 p.m.—Dr. W. T. Astbury, F.R.S.: "X-Ray Adventures among the Proteins and other Molecular Giants"; at 7.30 p.m.—Programme of New Scientific Films.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR (full-time) IN PHYSIOLOGY—The Registrar, The University, Liverpool (August 31).

CHEMICAL ENGINEER for a responsible appointment on the Technical Staff of an established Firm of Contractors to Gas and Allied Industries—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting C.2646 XA (August 31).

DEMONSTRATORS, one in the DIVISION OF CHEMISTRY, and one in the DIVISION OF HISTOLOGY, at the Royal Veterinary College, Camden Town, London, N.W.1—The Bursar, Royal Veterinary College, The University, Reading (September 1).

ENGINEERING ASSISTANT in the County Architect's Department—The County Architect, 4 Alfred Street North, Carlisle (September 3)

PHYSICIST (male) for position as RESEARCH SCIENTIST in Laboratory on work connected with magnetic properties of alloys—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting A 950.XA (September 7).

ASSISTANT INSPECTORS (2, male) OF FISHERIES in the Department of Agriculture—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (September 14).

EDUCATIONAL PSYCHOLOGIST—The Director of Education, Education Offices, Deansgate, Manchester 3 (September 14)

FOREST OFFICER in the Forestry Division of the Department of Agriculture, Southern Rhodesia—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (September 14).

LECTURER IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, The University, Sheffield (September 15).

ENGINEERING ASSISTANT—The Water Engineer and Manager, Spon House, 21 Allesley Old Road, Coventry, endorsed 'Engineering Assistant' (September 17).

COUNTY ANALYST AND OFFICIAL AGRICULTURAL ANALYST—The Clerk of the County Council, County Hall, Maidstone, Kent (October 6).

SUPERINTENDENT OF WORKSHOPS—The Secretary of the Appointments Committee, Engineering Laboratory, Cambridge (October 22)

GEORGE HOLT CHAIR OF PATHOLOGY—The Registrar, The University, Liverpool (October 31).

LECTURER (Grade B) IN PHYSIOLOGY—The Secretary, The University, Edinburgh (November 10).

LABORATORY ASSISTANTS in the Research Laboratories of the Royal Aircraft Establishment—The Personnel Department, Royal Aircraft Establishment, Farnborough, Hants.

MECHANICAL ENGINEERING ASSISTANT, with good experience of Diesel engines—The Mid-Kent Water Company, High Street, Snodland, Kent.

PRINCIPAL OF THE IMPERIAL COLLEGE OF TROPICAL AGRICULTURE, Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2.

HEAD TEACHER OF MATHEMATICS—The Principal, La Martinière College, Lucknow, India.

GRADUATE TEACHER for GENERAL SCIENCE, PHYSICS and CHEMISTRY—The Principal, Technical College, Wolverton, Bucks.

LECTURERS (2) IN MECHANICAL ENGINEERING SUBJECTS to Higher National Certificate standard at the Crewe Technical College—The Director of Education, County Education Offices, City Road, Chester

ASSISTANT MASTER to teach ENGINEERING SCIENCE, GENERAL SCIENCE and MATHEMATICS—The Clerk to the Governors, Grays County Technical School, 22 High View Avenue, Grays, Essex

GRADUATE LECTURER IN ENGINEERING, and a GRADUATE LECTURER with high qualifications in ORGANIC CHEMISTRY to take the subject to A.R.I.C. and Special B.Sc.(Lond.) standard—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

TEACHER OF MATHEMATICS, mainly for Day Technical School—The Principal, Beckenham Technical Institute, Beckenham, Kent.

GRADUATE TEACHER OF SCIENCE (chiefly PHYSICS) with so MATHEMATICS or of MATHEMATICS with some SCIENCE—The Principa Technical Institute, Darnley Road, Gravesend.

TEACHER FOR ENGINEERING SUBJECTS—The Principal and Secreta Harris Institute, Preston.

ASSISTANT LECTURER IN THE METALLURGY DEPARTMENT, and a ASSISTANT LECTURER IN ENGINEERING, for Workshop Technology a Practice, in the Swansea Technical College—The Director of Educatio Guildhall, Swansea

LECTURER IN MECHANICAL ENGINEERING for work up to the standa of the Higher National Certificate, particularly in Theory of Machin and Heat Engines—The Principal, Wimbledon Technical Colleg Gladstone Road, London, S.W.19.

LECTURER IN AGRICULTURE—The Principal, Kent Farm Institut Sittingbourne, Kent.

ASSISTANT TO THE ADVISORY CHEMIST in the Faculty Agriculture and Horticulture—The Registrar, The University, Readin
